About the Author

Al Sweigart is a software developer, author, and Fellow of the Python Software Foundation. He was previously the education director at Oakland, California's video game museum, The Museum of Art and Digital Entertainment. He has written several programming books, including *Automate the Boring Stuff with Python* and *Invent Your Own Computer Games with Python*. His books are freely available under a Creative Commons license at his website <https://inventwithpython.com>. His cat Zophie loves eating nori seaweed snacks.

About the Technical Reviewer

Sarah Kuchinsky, MS, is a corporate trainer and consultant. She uses Python for a variety of applications, including health systems modeling, game development, and task automation. Sarah is a co-founder of the North Bay Python conference, tutorials chair for PyCon US, and lead organizer for PyLadies Silicon Valley. She holds degrees in Management Science & Engineering and Mathematics.

CONTENTS IN DETAIL

Introduction	xv
Project 1, Bagels: Deduce a secret three-digit number based on clues. <i>Practice using constants.</i>	1
Project 2, Birthday Paradox: Determine the probability that two people share the same birthday in groups of different sizes. <i>Use Python's datetime module.</i>	6
Project 3, Bitmap Message: Display a message on the screen configured by a 2D bitmap image. <i>Work with multiline strings.</i>	11
Project 4, Blackjack: A classic card game played against an AI dealer. <i>Learn about Unicode characters and code points.</i>	15
Project 5, Bouncing DVD Logo: Simulates the colorful bouncing DVD logo of decades past. <i>Work with coordinates and colorful text.</i>	23
Project 6, Caesar Cipher: A simple encryption scheme used thousands of years ago. <i>Convert between letters and numbers to perform math on text.</i>	29
Project 7, Caesar Hacker: A program to decrypt Caesar cipher messages without the encryption key. <i>Implement a brute-force cryptanalysis algorithm.</i>	33
Project 8, Calendar Maker: Create calendar pages for a given year and month. <i>Use Python's datetime module and the timedelta data type.</i>	36
Project 9, Carrot in a Box: A silly bluffing game between two players. <i>Create ASCII art.</i>	41
Project 10, Cho-Han: A gambling dice game from feudal Japan. <i>Practice using random numbers and dictionary data structures.</i>	47

Project 11, Clickbait Headline Generator: A humorous headline generator for your content farm.	51
<i>Practice string manipulation and text generation.</i>	
Project 12, Collatz Sequence: Explore the simplest impossible conjecture in mathematics.	56
<i>Learn about the modulus operator.</i>	
Project 13, Conway's Game of Life: The classic cellular automata whose simple rules produce complex emergent behavior.	59
<i>Use dictionary data structures and screen coordinates.</i>	
Project 14, Countdown: A countdown timer with a seven-segment display.	63
<i>Practice importing modules you create.</i>	
Project 15, Deep Cave: A tunnel animation that descends endlessly into the earth.	66
<i>Use string replication and simple math.</i>	
Project 16, Diamonds: An algorithm for drawing diamonds of various sizes.	69
<i>Practice your pattern recognition skills to create drawing algorithms.</i>	
Project 17, Dice Math: A visual dice-rolling math game.	73
<i>Use dictionary data structures for screen coordinates.</i>	
Project 18, Dice Roller: A tool for reading <i>Dungeons & Dragons</i> dice notation to generate random numbers.	79
<i>Parse text to identify key strings.</i>	
Project 19, Digital Clock: A clock with a calculator-like display.	83
<i>Generate numbers that match information from the <code>datetime</code> module.</i>	
Project 20, Digital Stream: A scrolling screensaver that resembles <i>The Matrix</i> .	86
<i>Experiment with different animation speeds.</i>	
Project 21, DNA Visualization: An endless ASCII-art double helix that demonstrates the structure of DNA.	90
<i>Work with string templates and randomly generated text.</i>	
Project 22, Ducklings: Mix and match strings to create a variety of ASCII-art ducks.	94
<i>Use object-oriented programming to create a data model for duck drawings.</i>	

- Project 23, Etching Drawer:** Move the cursor to create line drawings. **100**
Work with screen coordinates and relative directional movements.
- Project 24, Factor Finder:** Find all the multiplicative factors of a number. **106**
Use the modulus operator and Python's math module.
- Project 25, Fast Draw:** Test your reflexes to see if you're the fastest keyboard in the West. **110**
Learn about the keyboard buffer.
- Project 26, Fibonacci:** Generate numbers in the famous Fibonacci sequence. **113**
Implement a rudimentary mathematics algorithm.
- Project 27, Fish Tank:** A colorful, animated ASCII-art fish tank. **117**
Use screen coordinates, text colors, and data structures.
- Project 28, Flooder:** Attempt to fill the entire puzzle board with one color. **125**
Implement the flood fill algorithm.
- Project 29, Forest Fire Sim:** Simulate the spread of wildfires through a forest. **132**
Create a simulation with adjustable parameters.
- Project 30, Four in a Row:** A board game where two players try to connect four tiles in a row. **137**
Create a data structure that mimics gravity.
- Project 31, Guess the Number:** The classic number guessing game. **143**
Program basic concepts for beginners.
- Project 32, Gullible:** A humorous program to keep gullible people busy for hours. **147**
Use input validation and loops.
- Project 33, Hacking Minigame:** Deduce a password based on clues. **150**
Add cosmetic features to make a basic game more interesting.
- Project 34, Hangman and Guillotine:** The classic word guessing game. **156**
Use string manipulation and ASCII art.
- Project 35, Hex Grid:** Programmatically generate tiled ASCII art. **162**
Use loops to make repeating text patterns.

Project 36, Hourglass: A simple physics engine for falling sand. <i>Simulate gravity and use collision detection.</i>	165
Project 37, Hungry Robots: Avoid killer robots in a maze. <i>Create a simple AI for robot movements.</i>	171
Project 38, J'Accuse!: A detective game to determine liars and truth-tellers. <i>Use data structures to generate relationships between suspects, places, and item clues.</i>	178
Project 39, Langton's Ant: A cellular automata whose ants move according to simple rules. <i>Explore how simple rules create complex graphical patterns.</i>	186
Project 40, Leetspeak: Translate English messages into l33t5p34]<. <i>Use text parsing and string manipulation.</i>	192
Project 41, Lucky Stars: A push-your-luck dice game. <i>Practice ASCII art and probability.</i>	195
Project 42, Magic Fortune Ball: A program to answer your yes/no questions about the future. <i>Add cosmetic features to make basic text appear more interesting.</i>	202
Project 43, Mancala: The ancient two-player board game from Mesopotamia. <i>Use ASCII art and string templates to draw a board game.</i>	206
Project 44, Maze Runner 2D: Try to escape a maze. <i>Read maze data from text files.</i>	213
Project 45, Maze Runner 3D: Try to escape a maze . . . in 3D! <i>Modify multiline strings to display a 3D view.</i>	219
Project 46, Million Dice Roll Statistics Simulator: Explore the probability results of rolling a set of dice one million times. <i>Learn how computers crunch large quantities of numbers.</i>	228
Project 47, Mondrian Art Generator: Create geometric drawings in the style of Piet Mondrian. <i>Implement an art-generating algorithm.</i>	231
Project 48, Monty Hall Problem: A simulation of the Monty Hall game show problem. <i>Examine probability with ASCII-art goats.</i>	238

Project 49, Multiplication Table: Display the multiplication table up to 12×12 .	245
<i>Practice spacing text.</i>	
Project 50, Ninety-Nine Bottles: Display the lyrics to a repetitive song.	248
<i>Use loops and string templates to produce text.</i>	
Project 51, niNety-nniinE BoOttels: Display the lyrics to a repetitive song that get more distorted with each verse.	251
<i>Manipulate strings to introduce distortions.</i>	
Project 52, Numeral Systems Counters: Examine binary and hexadecimal numbers.	255
<i>Use Python's number conversion functions.</i>	
Project 53, Periodic Table of the Elements: An interactive database of chemical elements.	259
<i>Parse CSV files to load data into a program.</i>	
Project 54, Pig Latin: Translates English messages into lgpay Atinlay.	263
<i>Use text parsing and string manipulation.</i>	
Project 55, Powerball Lottery: Simulate losing at the lottery thousands of times.	267
<i>Explore probability using random numbers.</i>	
Project 56, Prime Numbers: Calculate prime numbers.	272
<i>Learn math concepts and use Python's math module.</i>	
Project 57, Progress Bar: A sample progress bar animation to use in other programs.	275
<i>Use the backspace-printing technique to create animations.</i>	
Project 58, Rainbow: A simple rainbow animation.	279
<i>Create animation for beginners.</i>	
Project 59, Rock Paper Scissors: The classic hand game for two players.	282
<i>Implement basic game rules as a program.</i>	
Project 60, Rock Paper Scissors (Always-Win Version): A version of the game where the player cannot lose.	286
<i>Create the illusion of randomness in a program.</i>	

Project 61, ROT13 Cipher: The simplest cipher for encrypting and decrypting text.	290
<i>Convert between letters and numbers to perform math on text.</i>	
Project 62, Rotating Cube: A rotating cube animation.	293
<i>Learn 3D rotation and line drawing algorithms.</i>	
Project 63, Royal Game of Ur: A 5,000-year-old game from Mesopotamia.	300
<i>Use ASCII art and string templates to draw a board game.</i>	
Project 64, Seven-Segment Display Module: A display like those used in calculators and microwave ovens.	308
<i>Create modules for use in other programs.</i>	
Project 65, Shining Carpet: Programmatically generate the carpet from <i>The Shining</i> .	312
<i>Use loops to make repeating text patterns.</i>	
Project 66, Simple Substitution Cipher: An encryption scheme more advanced than the Caesar cipher.	315
<i>Perform intermediate math on text.</i>	
Project 67, Sine Message: Display a scrolling wave message.	320
<i>Use a trigonometry function for animation.</i>	
Project 68, Sliding Tile Puzzle: The classic four-by-four tile puzzle.	323
<i>Employ a data structure to reflect the state of a game board.</i>	
Project 69, Snail Race: Fast-paced snail racing action!	329
<i>Calculate spacing for ASCII art snails.</i>	
Project 70, Soroban Japanese Abacus: A computer simulation of a pre-computer calculating tool.	333
<i>Use string templates to create an ASCII-art counting tool.</i>	
Project 71, Sound Mimic: Memorize an increasingly long pattern of sounds.	339
<i>Play sound files from a Python program.</i>	
Project 72, sPOnGecAsE: Translates English messages into sPOnGecAsE.	343
<i>Change the casing of letters in strings.</i>	

Project 73, Sudoku Puzzle: The classic nine-by-nine newspaper deduction puzzle.	346
<i>Model a puzzle with a data structure.</i>	
Project 74, Text-to-Speech Talker: Make your computer talk to you!	353
<i>Use your operating system's text-to-speech engine.</i>	
Project 75, Three-Card Monte: The tricky fast-swapping card game that scammers play on tourists.	356
<i>Manipulate a data structure based on random movements.</i>	
Project 76, Tic-Tac-Toe: The classic two-player board game of Xs and Os.	361
<i>Create a data structure and helper functions.</i>	
Project 77, Tower of Hanoi: The classic disk-stacking puzzle.	365
<i>Use stack data structures to simulate a puzzle state.</i>	
Project 78, Trick Questions: A quiz of simple questions with misleading answers.	370
<i>Parse the user's text to recognize keywords.</i>	
Project 79, Twenty Forty-Eight: A casual tile matching game.	377
<i>Simulate gravity to make tiles "fall" in arbitrary directions.</i>	
Project 80, Vigenère Cipher: An encryption scheme so advanced it remained unbreakable for hundreds of years until computers were invented.	385
<i>Perform more advanced math on text.</i>	
Project 81, Water Bucket Puzzle: Obtain exactly four liters of water by filling and emptying three buckets.	390
<i>Use string templates to generate ASCII art.</i>	
Appendix A: Tag Index	395
Appendix B: Character Map	398

INTRODUCTION

Programming was so easy when it was just following `print('Hello, world!')` tutorials. Perhaps you've followed a well-structured book or online course for beginners, worked through the exercises, and nodded along with its technical jargon that you (mostly) understood. However, when it came time to leave the nest to write your own programs, maybe you found it hard to fly on your own. You found yourself staring at a blank editor window and unsure of how to get started writing Python programs of your own.

The problem is that following a tutorial is great for learning concepts, but that isn't necessarily the same thing as learning to create original programs from scratch. The common advice given at this stage is to examine the source code of open source software or to work on your own projects, but open source projects aren't always well documented or especially accessible to newcomers. And while it's motivating to work on your own project, you're left completely without guidance or structure.

This book provides you with practice examples of how programming concepts are applied, with a collection of over 80 games, simulations, and digital art programs. These aren't code snippets; they're full, runnable Python programs. You can copy their code to become familiar with how they work, experiment with your own changes, and then attempt to re-create them on your own as practice. After a while, you'll start to get ideas for your own programs and, more importantly, know how to go about creating them.

How to Design Small Programs

Programming has proven to be a powerful skill, creating billion-dollar tech companies and amazing technological advances. It's easy to want to aim high with your own software creations, but biting off more than you can chew can leave you with half-finished programs and frustration. However, you don't need to be a computer genius to code fun and creative programs.

The Python programs in this book follow several design principles to aid new programmers in understanding their source code:

Small Most of these programs are limited to 256 lines of code and are often significantly shorter. This size limit makes them easier to comprehend. The choice of 256 is arbitrary, but 256 is also 2^8 , and powers of 2 are lucky programmer numbers.

Text based Text is simpler than graphics. Since the source code and program output are both text, it's easy to trace the cause and effect between `print('Thanks for playing!')` in the code and `Thanks for playing!` appearing on the screen.

No installation needed Each program is self-contained in a single Python source file with the `.py` file extension, like `tictactoe.py`. You don't need to run an installer program, and you can easily post these programs online to share with others.

Numerous There are 81 programs in this book. Between board games, card games, digital artwork, simulations, mathematical puzzles, mazes, and humor programs, you're bound to find many things you'll love.

Simple The programs have been written to be easy to understand by beginners. Whenever I had to choose between writing code using sophisticated, high-performance algorithms or writing plain, straightforward code, I've chosen the latter every time.

The text-based programs may seem old school, but this style of programming cuts out the distractions and potholes that downloading graphics, installing additional libraries, and managing project folders bring. Instead, you can just focus on the code.

Who Is This Book For?

This book is written for two groups of people. The people in the first group are those who have already learned the basics of Python and programming

but are still unsure of how to write programs on their own. They may feel that programming hasn't "clicked" for them. They may be able to solve the practice exercises from their tutorials but still struggle to picture what a complete program "looks like." By first copying and then later re-creating the games in this book, they'll be exposed to how the programming concepts they've learned are assembled into a variety of real programs.

The people in the second group are those who are new to programming but are excited and a bit adventurous. They want to dive right in and get started making games, simulations, and number-crunching programs right away. They're fine with copying the code and learning along the way. Or perhaps they already know how to program in another language but are new to Python. While it's no substitute for a complete introductory Python course, this book contains a brief introduction to Python basics and how to use the debugger to examine the inner workings of a program as it runs.

Experienced programmers might have fun with the programs in this book as well, but keep in mind that this book was written for beginners.

About This Book

While the bulk of this book is dedicated to the featured programs, there are also extra resources with general programming and Python information. Here's what's contained in this book:

Projects The 81 projects are too numerous to list here, but each one is a self-contained mini-chapter that includes the project's name, a description, a sample run of the program's output, and the source code of the program. There are also suggestions for experimental edits you can make to the code to customize the program.

Appendix A: Tag Index Lists all of the projects categorized by their project tags.

Appendix B: Character Map A list of character codes for symbols such as hearts, lines, arrows, and blocks that your programs can print.

How to Learn from the Programs in This Book

This book doesn't teach Python or programming concepts like a traditional tutorial. It has a learn-by-doing approach, where you're encouraged to manually copy the programs, play with them, and inspect their inner workings by running them under a debugger.

The point of this book isn't to give a detailed explanation of programming language syntax, but to show solid examples of programs that perform an actual activity, whether it's a card game, an animation, or exploration of a mathematical puzzle. As such, I recommend the following steps:

1. Download the program and run it to see what the program does for yourself.

2. Starting from a blank file, copy the code of the game from this book by manually typing it yourself. (Don't use copy and paste!)
3. Run the program again, and go back and fix any typos or bugs you may have introduced.
4. Run the program under a debugger, so you can carefully execute each line of code one at a time to understand what it does.
5. Find the comments marked with (!) to find code that you can modify and then see how this affects the program the next time you run it.
6. Finally, try to re-create the program yourself from scratch. It doesn't have to be an exact copy; you can put your own spin on the program.

When copying the code from this book, you don't necessarily have to type the comments (the text at the end of a line following the # symbol), as these are notes for human programmers and are ignored by Python. However, try to write your Python code on the same line numbers as the programs in this book to make comparison between the two easier. If you have trouble finding typos in your program, you can compare your code to the code in this book with the online diff tool at <https://inventwithpython.com/bigbookpython/diff/>.

Each program has been given a set of tags to describe it, such as **board game**, **simulation**, **artistic**, and **two-player**. An explanation of each of these tags and a cross-index of tags and projects can be found in Appendix A. The projects are listed in alphabetical order, however.

Downloading and Installing Python

Python is the name of both the programming language and the interpreter software that runs your Python code. The Python software is completely free to download and use. You can check if you already have Python installed from a command line window. On Windows, open the Command Prompt program and then enter **py --version**. If you see output like the following, then Python is installed:

```
C:\Users\Al>py --version
Python 3.9.1
```

On macOS and Linux, open the Terminal program and then enter **python3 --version**. If you see output like the following, then Python is installed:

```
$ python3 --version
Python 3.9.1
```

This book uses Python version 3. Several backward-incompatible changes were made between Python 2 and 3, and the programs in this book require at least Python version 3.1.1 (released in 2009) to run. If you see an error message telling you that Python cannot be found or the version reports Python 2, you can download the latest Python installer for your

operating system from <https://python.org/>. If you're having trouble installing Python, you can find more instructions at <https://installpython3.com/>.

Downloading and Installing the Mu Editor

While the Python software runs your program, you'll type the Python code into a text editor or integrated development environment (IDE) application. I recommend using Mu Editor for your IDE if you are a beginner because it's simple and doesn't distract you with an overwhelming number of advanced options.

Open <https://codewith.mu/> in your browser. On Windows and macOS, download the installer for your operating system and then run it by double-clicking the installer file. If you are on macOS, running the installer opens a window where you must drag the Mu icon to the Applications folder icon to continue the installation. If you are on Ubuntu, you'll need to install Mu as a Python package. In that case, open a new Terminal window and run `pip3 install mu-editor` to install and `mu-editor` to run it. Click the **Instructions** button in the Python Package section of the download page for full instruction details.

Running the Mu Editor

Once it's installed, let's start Mu:

- On Windows 7 or later, click the **Start** icon in the lower-left corner of your screen, enter `mu` in the search box, and select **Mu** when it appears.
- On macOS, open the Finder window, click **Applications**, and then click **mu-editor**.
- On Ubuntu, press CTRL-ALT-T to open a Terminal window and then enter `python3 -m mu`.

The first time Mu runs, a Select Mode window appears with the following options: Adafruit CircuitPython, BBC micro:bit, Pygame Zero, and Python 3. Select Python 3. You can always change the mode later by clicking the **Mode** button at the top of the editor window.

You'll be able to enter the code into Mu's main window and then save, open, and run your files from the buttons at the top.

Running IDLE and Other Editors

You can use any number of editors for writing Python code. The Integrated Development and Learning Environment (IDLE) software installs along with Python, and it can serve as a second editor if for some reason you can't get Mu installed or working. Let's start IDLE now:

- On Windows 7 or later, click the **Start** icon in the lower-left corner of your screen, enter `idle` in the search box, and select **IDLE (Python GUI)**.

- On macOS, open the Finder window and click **Applications** ▶ **Python 3.9** ▶ **IDLE**.
- On Ubuntu, select **Applications** ▶ **Accessories** ▶ **Terminal** and then enter `idle3`. (You may also be able to click **Applications** at the top of the screen, select **Programming**, and then click **IDLE 3**.)
- On the Raspberry Pi, click the Raspberry Pi menu button in the top-left corner; then click **Programming** and **Python 3 (IDLE)**. You can also select **Thonny Python IDE** from under the **Programming** menu.

There are several other free editors you can use to enter and run Python code, such as:

- Thonny, a Python IDE for beginners, at <https://thonny.org/>.
- PyCharm Community Edition, a Python IDE used by professional developers, at <https://www.jetbrains.com/pycharm/>.

Installing Python Modules

Most of the programs in this book only require the Python Standard Library, which is installed automatically with Python. However, some programs require third-party modules such as `pyperclip`, `bext`, `playsound`, and `pyttsx3`. All of these can be installed at once by installing the `bigbookpython` module.

For the Mu Editor, you must install the 1.1.0-alpha version (or later). As of 2020, you can find this version at the top of the download page at <https://codewith.mu/en/download> under the “Try the Alpha of the Next Version of Mu” section. After installation, click the gear icon in the lower-left corner of the window to bring up the Mu Administration window. Select the **Third Party Packages** tab, enter `bigbookpython` into the text field, and click **Ok**. This installs all of the third-party modules used by the programs in this book.

For the Visual Studio Code or IDLE editor, open the editor and run the following Python code from the interactive shell:

```
>>> import os, sys
>>> os.system(sys.executable + ' -m pip install --user bigbookpython')
0
```

The number `0` appears after the second instruction if everything worked correctly. Otherwise, if you see an error message or another number, try running the following instructions, which don't have the `--user` option:

```
>>> import os, sys
>>> os.system(sys.executable + ' -m pip install bigbookpython')
0
```

No matter which editor you use, you can try running `import pyperclip` or `import bext` to check if the installation worked. If these import instructions don't produce an error message, these modules installed correctly and you'll be able to run the projects in this book that use these modules.

Copying the Code from This Book

Programming is a skill that you improve by programming. Don't just read the code in this book or copy and paste it to your computer. Take the time to enter the code into the editor for yourself. Open a new file in your code editor and enter the code. Pay attention to the line numbers in this book and your editor to make sure you aren't accidentally skipping any lines. **If you encounter errors, use the online diff tool at <https://inventwithpython.com/bigbookpython/diff/> to show you any differences between your code and the code in this book.** To get a better understanding of these programs, try running them under the debugger.

After entering the source code and running it a few times, try making experimental changes to the code. The comments marked with (!) have suggestions for small changes you can make, and each project lists suggestions for larger modifications.

Next, try re-creating the program from scratch without looking at the source code in this book. It doesn't have to be exactly the same as this program; you can invent your own version!

Once you've worked through the programs in this book, you might want to start creating your own. Most modern video games and software applications are complicated, requiring teams of programmers, artists, and designers to create. However, many board, card, and paper-and-pencil games are often simple enough to re-create as a program. Many of these fall under the category of "abstract strategy games." You can find a list of them at https://en.wikipedia.org/wiki/List_of_abstract_strategy_games.

Running Programs from the Terminal

The programming projects in this book that use the `bext` module have colorful text for their output. However, these colors won't appear when you run them from Mu, IDLE, or other editors. These programs should be run from a *terminal*, also called *command line*, window. On Windows, run the Command Prompt program from the Start menu. On macOS, run Terminal from Spotlight. On Ubuntu Linux, run Terminal from Ubuntu Dash or press CTRL-ALT-T.

When the terminal window appears, you should change the current directory to the folder with your `.py` files with the `cd` (change directory) command. (*Directory* is another term for folder.) For example, if I were on Windows and saved my Python programs to the `C:\Users\Al` folder, I would enter the following line.

```
C:\>cd C:\Users\Al
```

```
C:\Users\Al>
```

Then, to run Python programs, enter `python yourProgram.py` on Windows or `python3 yourProgram.py` on macOS and Linux, replacing *yourProgram.py* with the name of your Python program:

```
C:\Users\Al>python guess.py
Guess the Number, by Al Sweigart al@inventwithpython.com
```

```
I am thinking of a number between 1 and 100.
You have 10 guesses left. Take a guess.
--snip--
```

You can terminate programs run from the terminal by pressing CTRL-C rather than close the terminal window itself.

Running Programs from a Phone or Tablet

Ideally you'll have a laptop or desktop computer with a full keyboard to write code, as tapping on a phone or even tablet keyboard can be tedious. While there are no established Python interpreters for Android or iOS, there are websites that host online Python interactive shells you can use from a web browser. These will also work for laptops and desktops, in case you're an instructor who doesn't have account permission to install new software on your classroom's computers.

The websites <https://repl.it/languages/Python3/> and <https://www.pythonanywhere.com/> have Python interpreters that are free to use in your web browser. These websites will work with most of the projects in this book. However, they won't work with programs that make use of third-party modules, such as `bext`, `pyperclip`, `pyttsx3`, and `playsound`. They also won't work with programs that need to read or write files with the `open()` function. If you see these terms in the program's code, the program won't work in these online Python interpreters. However, the majority of programs in this book will work just fine.

How to Get Help

Unless you can hire a private tutor or have a programmer friend who can answer your programming questions, you'll need to rely on yourself to find answers to your questions. Fortunately, your questions have almost certainly been asked before. Being able to find answers on your own is an important skill for programmers to learn.

Don't feel discouraged if you find yourself constantly looking up answers to your programming questions online. You may feel like it's "cheating" to check online instead of memorizing everything about programming from

the start, but as long as you're learning, it's not cheating. Even professional software developers search the internet on a daily basis. In this section, you'll learn how to ask smart questions and search for answers on the internet.

When your program tries to carry out an invalid instruction, it displays an error message called a traceback. The traceback tells you what kind of error occurred and which line of code the error occurred on. Here's an example of a program that had an error while calculating how many slices of pizza each person should get:

```
Traceback (most recent call last):
  File "pizza.py", line 5, in <module>
    print('Each person gets', (slices / people), ' slices of pizza.')
ZeroDivisionError: division by zero
```

From this traceback, you might not realize that the problem is that the `people` variable is set to 0, and so the expression `slices / people` caused a zero-divide error. Error messages are often so short they're not even full sentences. Since programmers encounter them regularly, they're intended as reminders rather than full explanations. If you're encountering an error message for the first time, copying and pasting it into an internet search often returns a detailed explanation of what the error means and what its likely causes are.

If you're unable to find the solution to your problem by searching the internet, you can post your question to an online forum or email someone. To make this process as efficient as possible, ask specific, well-stated questions. This means providing full source code and error message details, explaining what you've already tried, and telling your helper what operating system and version of Python you're using. Not only will the posted answers solve your problem, but they can help future programmers who have your same question and find your post.

Typing Code

You don't have to be able to type fast to be a programmer, but it helps. While many people take a "hunt and peck" approach to typing, a faster typing speed can make programming less of a chore. As you work through the programs in this book, you'll want your eyes on the code and not on your keyboard.

There are free websites for learning how to type, such as <https://typing.club.com/> or <https://www.typing.com/>. A good typing program will display a keyboard and transparent hands on the screen so you can practice without the bad habit of looking down at the keyboard to find keys. Like every skill, typing is a matter of practice, and writing code can provide you with plenty of opportunities to type.

Keyboard shortcuts allow you to perform actions in a fraction of the time it takes to move the mouse to a menu and perform the action. A shortcut is often written like "CTRL-C," which means pressing down one of the

two CTRL keys on either side of the keyboard and then pressing the C key. It does not mean pressing the CTRL key once, followed by pressing the C key.

You can discover the common shortcuts, such as CTRL-S to save and CTRL-C to copy, by using the mouse to open the menu bar at the top of the application (in Windows and Linux) or top of the screen (in macOS). It's well worth the time to learn and use these keyboard shortcuts.

Other shortcuts are not so obvious. For example, ALT-TAB on Windows and Linux and COMMAND-TAB on macOS allow you to switch focus to another application's window. You can hold the ALT or COMMAND key down and repeatedly press TAB to select a specific window to switch to.

Copying and Pasting

The *clipboard* is a feature of your operating system that can temporarily store data for pasting. While this data can be text, images, files, or other types of information, we'll be dealing with text data in this section. *Copying* text places a copy of the currently selected text onto the clipboard. *Pasting* text enters the text on the clipboard into wherever the text cursor currently is, as though you had instantly typed it yourself. Copying and pasting text frees you from having to retype text that already exists on your computer, whether it's a single line or hundreds of pages.

To copy and paste text, first select, or *highlight*, the text to copy. You can do this by holding down the primary mouse button (which is the left button, if the mouse is set for right-handed users) and dragging over the text to select it. However, holding down the SHIFT key and moving the cursor with the keyboard shortcuts is often faster and more precise. Many applications allow you to double-click a word to immediately select the entire word. You can also often triple-click to immediately select an entire line or paragraph.

The next step is to press CTRL-C on Windows or COMMAND-C on macOS to copy the selected text to the clipboard. The clipboard can only hold one selection of text, so copying text replaces anything that was previously on the clipboard.

Finally, move the cursor to where you want the text to appear and press CTRL-V on Windows or COMMAND-V on macOS to paste the text. You can paste as many times as you want; the text remains on the clipboard until you copy new text to replace it.

Finding and Replacing Text

Dan Russell, a search anthropologist at Google, explained in a 2011 *Atlantic* article that when he studied people's computer usage habits, 90 percent of them didn't know they could press CTRL-F (on Windows and Linux) or COMMAND-F (on macOS) to search for words in their applications. This is an incredibly useful feature, not just in code editors, but in word processors, web browsers, spreadsheet applications, and almost every kind

of program that displays text. You can press CTRL-F to bring up a Find window to enter a word to find in the program. Often the F3 key will repeat this search to highlight the next occurrence of the word. This feature can save you an extraordinary amount of time compared to manually scrolling through your document to find a word.

Editors also have a find-and-replace feature, which is often assigned the CTRL-H or COMMAND-H shortcut. This allows you to locate occurrences of one bit of text and replace it with another. This is useful if you want to rename a variable or function. However, you need to be careful using the find-and-replace feature because you could unintentionally replace text that matched your find criteria by coincidence.

The Debugger

A debugger is a tool that runs programs one line at a time and lets you inspect the current state of the program's variables. It's a valuable tool for tracking down bugs. This section will explain the features of the Mu Editor's debugger. Don't worry; every debugger will have these same features, even if the user interface looks different.

To start a program in the debugger, use the Debug menu item in your IDE instead of the Run menu item. The debugger will start in a paused state on the first line of your program. All debuggers have the following buttons: Continue, Step In, Step Over, Step Out, and Stop.

Clicking the Continue button causes the program to execute normally until it terminates or reaches a breakpoint. (I describe breakpoints later in this section.) If you are done debugging and want the program to continue normally, click the Continue button.

Clicking the Step In button causes the debugger to execute the next line of code and then pause again. If the next line of code is a function call, the debugger will "step into" that function and jump to the first line of code of that function.

Clicking the Step Over button executes the next line of code, similar to the Step In button. However, if the next line of code is a function call, the Step Over button will "step over" the code in the function. The function's code executes at full speed, and the debugger will pause as soon as the function call returns. Using the Step Over button is more common than using the Step In button.

Clicking the Step Out button causes the debugger to execute lines of code at full speed until it returns from the current function. If you have stepped into a function call with the Step In button and now simply want to keep executing instructions until you get back out, click the Step Out button to "step out" of the current function call.

If you want to stop debugging entirely and not bother to continue executing the rest of the program, click the Stop button. The Stop button immediately terminates the program.

You can set a *breakpoint* on a particular line and let the program run at normal speed until it reaches the breakpoint line. At that point, the

debugger pauses to let you inspect the variables and lets you resume stepping through individual lines of code. In most IDEs, you can set a breakpoint by double-clicking the line numbers on the left side of the window.

The values currently stored in the program's variables are displayed somewhere in the debugging window in every debugger. However, one common method of debugging your programs is *print debugging*: adding `print()` calls to display the values of variables and then rerunning your program. While simple and convenient, this approach to debugging can often be slower than using a debugger. With print debugging, you must add the `print()` calls, rerun your program, and then remove the `print()` calls later. However, after rerunning the program, you'll often find that you need to add more `print()` calls to see the values of other variables. This means you need to rerun the program yet again, and this run could reveal that you need another round of adding `print()` calls, and so on. Also, it's common to forget some of the `print()` calls you've added, requiring an additional round of deleting `print()` calls. Print debugging is straightforward for simple bugs, but using an actual debugger can save you time in the long run.

Summary

Programming is a fun, creative skill to develop. Whether you've mastered the basics of Python syntax or simply want to dive into some real Python programs, the projects in this book will spark new ideas for what's possible with as little as a few pages of code.

The best way to work through these programs isn't to merely read their code or copy and paste it to your computer. Take the time to manually type the code from this book into your editor to develop the muscle memory of writing code. This also slows you down so you can consider each line as you type, instead of merely skimming it over with your eyes. Look up any instructions you don't recognize using an internet search engine, or experiment with them in the interactive shell.

Finally, take it upon yourself to re-create the program from scratch and then modify it with features of your own. These exercises give you a solid foundation for how programming concepts are applied to create actual, runnable programs. And most of all, don't forget to have fun!

BAGELS

In Bagels, a deductive logic game, you must guess a secret three-digit number based on clues. The game offers one of the following hints in response to your guess: “Pico” when your guess has a correct digit in the wrong place, “Fermi” when your guess has a correct digit in the correct place, and “Bagels” if your guess has no correct digits. You have 10 tries to guess the secret number.

The Program in Action

When you run *bagels.py*, the output will look like this:

```
Bagels, a deductive logic game.
By Al Sweigart al@inventwithpython.com

I am thinking of a 3-digit number. Try to guess what it is.
Here are some clues:
When I say:    That means:
    Pico           One digit is correct but in the wrong position.
    Fermi          One digit is correct and in the right position.
    Bagels         No digit is correct.
I have thought up a number.
You have 10 guesses to get it.
Guess #1:
> 123
Pico
Guess #2:
> 456
Bagels
Guess #3:
> 178
Pico Pico
--snip--
Guess #7:
> 791
Fermi Fermi
Guess #8:
> 701
You got it!
Do you want to play again? (yes or no)
> no
Thanks for playing!
```

How It Works

Keep in mind that this program uses not integer values but rather string values that contain numeric digits. For example, '426' is a different value than 426. We need to do this because we are performing string comparisons with the secret number, not math operations. Remember that '0' can be a leading digit: the string '026' is different from '26', but the integer 026 is the same as 26.

87.         return 'Bagels' # There are no correct digits at all.
88.     else:
89.         # Sort the clues into alphabetical order so their original order
90.         # doesn't give information away.
91.         clues.sort()
92.         # Make a single string from the list of string clues.
93.         return ' '.join(clues)
94.
95.
96. # If the program is run (instead of imported), run the game:
97. if __name__ == '__main__':
98.     main()

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Change the number of digits for the secret number by changing NUM_DIGITS.
- Change the number of guesses the player gets by changing MAX_GUESSES.
- Try to create a version with letters as well as digits in the secret number.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens when you change the NUM_DIGITS constant?

2. What happens when you change the `MAX_GUESSES` constant?
3. What happens if you set `NUM_DIGITS` to a number larger than 10?
4. What happens if you replace `secretNum = getSecretNum()` on line 30 with `secretNum = '123'`?
5. What error message do you get if you delete or comment out `numGuesses = 1` on line 34?
6. What happens if you delete or comment out `random.shuffle(numbers)` on line 62?
7. What happens if you delete or comment out `if guess == secretNum:` on line 74 and `return 'You got it!'` on line 75?
8. What happens if you comment out `numGuesses += 1` on line 44?

#2

BIRTHDAY PARADOX

The Birthday Paradox, also called the Birthday Problem, is the surprisingly high probability that two people will have the same birthday even in a small group of people.

In a group of 70 people, there's a 99.9 percent chance of two people having a matching birthday. But even in a group as small as 23 people, there's a 50 percent chance of a matching birthday. This program performs several probability experiments to determine the percentages for groups of different sizes. We call these types of experiments, in which we conduct multiple random trials to understand the likely outcomes, Monte Carlo experiments.

You can find out more about the Birthday Paradox at https://en.wikipedia.org/wiki/Birthday_problem.

The Program in Action

When you run *birthdayparadox.py*, the output will look like this:

```

Birthday Paradox, by Al Sweigart al@inventwithpython.com
--snip--
How many birthdays shall I generate? (Max 100)
> 23

Here are 23 birthdays:
Oct 9, Sep 1, May 28, Jul 29, Feb 17, Jan 8, Aug 18, Feb 19, Dec 1, Jan 22,
May 16, Sep 25, Oct 6, May 6, May 26, Oct 11, Dec 19, Jun 28, Jul 29, Dec 6,
Nov 26, Aug 18, Mar 18

In this simulation, multiple people have a birthday on Jul 29

Generating 23 random birthdays 100,000 times...
Press Enter to begin...
Let's run another 100,000 simulations.
0 simulations run...
10000 simulations run...
--snip--
90000 simulations run...
100000 simulations run.
Out of 100,000 simulations of 23 people, there was a
matching birthday in that group 50955 times. This means
that 23 people have a 50.95 % chance of
having a matching birthday in their group.
That's probably more than you would think!
```

How It Works

Running 100,000 simulations can take a while, which is why lines 95 and 96 report that another 10,000 simulations have finished. This feedback can assure the user that the program hasn't frozen. Notice that some of the integers, like `10_000` on line 95 and `100_000` on lines 93 and 103, have underscores. These underscores have no special meaning, but Python allows them so that programmers can make integer values easier to read. In other words, it's easier to read "one hundred thousand" from `100_000` than from `100000`.

104. print('Out of 100,000 simulations of', numBDays, 'people, there was a')
105. print('matching birthday in that group', simMatch, 'times. This means')
106. print('that', numBDays, 'people have a', probability, '% chance of')
107. print('having a matching birthday in their group.')
108. print('That\'s probably more than you would think!')

```

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. How are birthdays represented in this program? (Hint: look at line 16.)
2. How could you remove the maximum limit of 100 birthdays the program generates?

3. What error message do you get if you delete or comment out `numBDays = int(response)` on line 57?
4. How can you make the program display full month names, such as 'January' instead of 'Jan'?
5. How could you make 'x simulations run...' appear every 1,000 simulations instead of every 10,000?

#3

BITMAP MESSAGE

This program uses a multiline string as a *bitmap*, a 2D image with only two possible colors for each pixel, to determine how it should display a message from the user. In this bitmap, space characters represent an empty space, and all other characters are replaced by characters in the user's message. The provided bitmap resembles a world map, but you can change this to any image you'd like. The binary simplicity of the space-or-message-characters system makes it good for beginners. Try experimenting with different messages to see what the results look like!

The Program in Action

When you run *bitmapmessage.py*, the output will look like this:

```
Bitmap Message, by Al Sweigart al@inventwithpython.com
Enter the message to display with the bitmap.
> Hello!

Hello!Hello!Hello!Hello!Hello!Hello!Hello!Hello!Hello!Hello!Hello!He
  lo!Hello!Hello  l !He lo e    llo!Hello!Hello!Hello!Hello!He
    llo!Hello!Hello!Hello He lo H l !Hello!Hello!Hello!Hello!Hello H
el      lo!Hello!Hello!He      lo!Hello!Hello!Hello!Hello!Hel
      o!Hello!Hello      lo e lo!H ll !Hello!Hello!H l
        !Hello!He          llo!Hel  Hello!Hello!Hell ! e
          Hello!He        ello!Hello!Hello!Hello!Hell H
1      H llo! ell        ello!Hello!Hell !Hello el o
        lo!H l          ello!Hello!Hell  ell !He o
          !Hello        llo!Hello!Hel  el He o
            !Hello!H    lo!Hello!Hell  l !H llo
              ello!Hel    Hello!He    H llo Hell
                ello!Hell    ello!H l    Hell !H l o!
                  ello!Hell    ello!H l o    o!H l H
                    lo!Hel    ello! el    o!Hel H
                      lo!He    llo! e    llo!Hell
                        llo!H    llo!    llo!Hello
                          llo!    ll    lo!Hell e
                            llo    l    l e
                              ll l H
Hello!Hello!Hello!Hello!Hello!Hello!Hello!Hello!Hello!Hello!Hello!He
```

How It Works

Instead of individually typing each character of the world map pattern, you can copy and paste the whole thing from <https://inventwithpython.com/bitmapworld.txt>. A line of 68 periods at the top and bottom of the pattern acts as a ruler to help you align it correctly. However, the program will still work if you make typos in the pattern.

The `bitmap.splitlines()` method call on line 43 returns a list of strings, each of which is a line in the multiline bitmap string. Using a multiline string makes the bitmap easier to edit into whatever pattern you like. The program fills in any non-space character in the pattern, which is why asterisks, periods, or any other character do the same thing.

The `message[i % len(message)]` code on line 51 causes the repetition of the text in `message`. As `i` increases from 0 to a number larger than `len(message)`, the expression `i % len(message)` evaluates to 0 again. This causes `message[i % len(message)]` to repeat the characters in `message` as `i` increases.

31.      **** * * ***** *
32.      *** * * * *
33.      ** * * * *
34. .... """
35.
36. print('Bitmap Message, by Al Sweigart al@inventwithpython.com')
37. print('Enter the message to display with the bitmap.')
38. message = input('> ')
39. if message == '':
40.     sys.exit()
41.
42. # Loop over each line in the bitmap:
43. for line in bitmap.splitlines():
44.     # Loop over each character in the line:
45.     for i, bit in enumerate(line):
46.         if bit == ' ':
47.             # Print an empty space since there's a space in the bitmap:
48.             print(' ', end='')
49.         else:
50.             # Print a character from the message:
51.             print(message[i % len(message)], end='')
52.     print() # Print a newline.

```

After entering the source code and running it a few times, try making experimental changes to it. You can change the string in `bitmap` to create entirely new patterns.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if the player enters a blank string for the message?
2. Does it matter what the nonspace characters are in the bitmap variable's string?
3. What does the `i` variable created on line 45 represent?
4. What bug happens if you delete or comment out `print()` on line 52?

#4

BLACKJACK

Blackjack, also known as 21, is a card game where players try to get as close to 21 points as possible without going over. This program uses images drawn with text characters, called *ASCII art*. American Standard Code for Information Interchange (ASCII) is a mapping of text characters to numeric codes that computers used before Unicode replaced it. The playing cards in this program are an example of ASCII art:

A	10
♣	♦
A	10

You can find other rules and the history of this card game at <https://en.wikipedia.org/wiki/Blackjack>.

The Program in Action

When you run *blackjack.py*, the output will look like this:

Blackjack, by Al Sweigart al@inventwithpython.com

Rules:

Try to get as close to 21 without going over.

Kings, Queens, and Jacks are worth 10 points.

Aces are worth 1 or 11 points.

Cards 2 through 10 are worth their face value.

(H)it to take another card.

(S)tand to stop taking cards.

On your first play, you can (D)ouble down to increase your bet but must hit exactly one more time before standing.

In case of a tie, the bet is returned to the player.

The dealer stops hitting at 17.

Money: 5000

How much do you bet? (1-5000, or QUIT)

> **400**

Bet: 400

DEALER: ???

```
|##| |2|
|###| |♥|
|_##| |_2|
```

PLAYER: 17

```
|K| |7|
|♠| |♦|
|_K| |_7|
```

(H)it, (S)tand, (D)ouble down

> **h**

You drew a 4 of ♦.

--snip--

DEALER: 18

```
|K| |2| |6|
|♦| |♥| |♠|
|_K| |_2| |_6|
```

PLAYER: 21

```
|K| |7| |4|
|♠| |♦| |♦|
|_K| |_7| |_4|
```

You won \$400!

--snip--

How It Works

The card suit symbols don't exist on your keyboard, which is why we call the `chr()` function to create them. The integer passed to `chr()` is called a Unicode *code point*, a unique number that identifies a character according to the Unicode standard. Unicode is often misunderstood. However, Ned Batchelder's 2012 PyCon US talk "Pragmatic Unicode, or How Do I Stop the Pain?" is an excellent introduction to Unicode, and you can find it at <https://youtu.be/sgHbC6udIqc/>. Appendix B gives a full list of Unicode characters you can use in your Python programs.

235.             if move == 'D' and '(D)ouble down' in moves:
236.                 return move # Player has entered a valid move.
237.
238.
239.     # If the program is run (instead of imported), run the game:
240.     if __name__ == '__main__':
241.         main()

```

After entering the source code and running it a few times, try making experimental changes to it. Blackjack has several custom rules that you could implement. For example, if the first two cards have the same value, a player can split them into two hands and wager on them separately. Also, if the player receives a “blackjack” (the ace of spades and a black jack) for their first two cards, the player wins a ten-to-one payout. You can find out more about the game from <https://en.wikipedia.org/wiki/Blackjack>.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. How can you make the player start with a different amount of money?
2. How does the program prevent the player from betting more money than they have?

3. How does the program represent a single card?
4. How does the program represent a hand of cards?
5. What do each of the strings in the rows list (created on line 197) represent?
6. What happens if you delete or comment out `random.shuffle(deck)` on line 148?
7. What happens if you change `money -= bet` on line 112 to `money += bet`?
8. What happens when `showDealerHand` in the `displayHands()` function is set to `True`? What happens when it is `False`?

#5

BOUNCING DVD LOGO

If you are of a certain age, you'll remember those ancient technological devices called DVD players. When not playing DVDs, they would display a diagonally traveling DVD logo that bounced off the edges of the screen. This program simulates this colorful DVD logo by making it change direction each time it hits an edge. We'll also keep track of how many times a logo hits a corner of the screen. This creates an interesting visual animation to look at, especially for the magical moment when a logo lines up perfectly with a corner.

You can't run this program from your integrated development environment (IDE) or editor because it uses the `bext` module. Therefore, it must be run from the Command Prompt or Terminal in order to display correctly. You can find more information about the `bext` module at <https://pypi.org/project/bext/>.

The Program in Action

When you run `bouncingdvd.py`, the output will look like Figure 5-1.

Figure 5-1: The diagonally moving DVD logos of the `bouncingdvd.py` program

How It Works

You may remember Cartesian coordinates from your math class in school. In programming, the x-coordinate represents an object's horizontal position and the y-coordinate represents its vertical position, just like in mathematics. However, unlike in mathematics, the origin point $(0, 0)$ is in the upper-left corner of the screen, and the y-coordinate increases as you go down. The x-coordinate increases as the object moves right, just like in mathematics. Figure 5-2 shows the coordinate system for your screen.

Figure 5-2: The origin point (0, 0) is in the upper left of the screen, while the x- and y-coordinates increase going right and down, respectively.

The `bext` module's `goto()` function works the same way: calling `bext.goto(0, 0)` places the text cursor at the top left of the terminal window. We represent each bouncing DVD logo using a Python dictionary with the keys 'color', 'direction', 'x', and 'y'. The values for the 'x' and 'y' are integers representing the logo's position in the window. Since these values get passed to `bext.goto()`, increasing them will move the logo right and down, while decreasing them will move the logo left and up.

116.            logo[Y] -= 1
117.        elif logo[DIR] == DOWN_RIGHT:
118.            logo[X] += 2
119.            logo[Y] += 1
120.        elif logo[DIR] == DOWN_LEFT:
121.            logo[X] -= 2
122.            logo[Y] += 1
123.
124.        # Display number of corner bounces:
125.        bext.goto(5, 0)
126.        bext.fg('white')
127.        print('Corner bounces:', cornerBounces, end='')
128.
129.    for logo in logos:
130.        # Draw the logos at their new location:

```

```

131.         bext.goto(logo[X], logo[Y])
132.         bext.fg(logo[COLOR])
133.         print('DVD', end='')
134.
135.     bext.goto(0, 0)
136.
137.     sys.stdout.flush() # (Required for bext-using programs.)
138.     time.sleep(PAUSE_AMOUNT)
139.
140.
141. # If this program was run (instead of imported), run the game:
142. if __name__ == '__main__':
143.     try:
144.         main()
145.     except KeyboardInterrupt:
146.         print()
147.         print('Bouncing DVD Logo, by Al Sweigart')
148.         sys.exit() # When Ctrl-C is pressed, end the program.

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Change `NUMBER_OF_LOGOS` to increase the number of bouncing logos on the screen.
- Change `PAUSE_AMOUNT` to speed up or slow down the logos.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `WIDTH, HEIGHT = bext.size()` on line 20 to `WIDTH, HEIGHT = 10, 5`?
2. What happens if you replace `DIR: random.choice(DIRECTIONS)` on line 52 with `DIR: DOWN_RIGHT`?
3. How can you make the 'Corner bounces:' text not appear on the screen?
4. What error message do you get if you delete or comment out `cornerBounces = 0` on line 57?

#6

CAESAR CIPHER

The Caesar cipher is an ancient encryption algorithm used by Julius Caesar. It encrypts letters by shifting them over by a certain number of places in the alphabet. We call the length of shift the *key*. For example, if the key is 3, then *A* becomes *D*, *B* becomes *E*, *C* becomes *F*, and so on. To decrypt the message, you must shift the encrypted letters in the opposite direction. This program lets the user encrypt and decrypt messages according to this algorithm.

In modern times, the Caesar cipher isn't very sophisticated, but that makes it ideal for beginners. The program in Project 7, "Caesar Hacker," can brute-force through all 26 possible keys to decrypt messages, even if you don't know the original key. Also, if you encrypt the message with the key 13, the Caesar cipher becomes identical to Project 61, "ROT 13 Cipher."

Learn more about the Caesar cipher at https://en.wikipedia.org/wiki/Caesar_cipher. If you'd like to learn about ciphers and code breaking in general, you can read my book *Cracking Codes with Python* (No Starch Press, 2018; <https://nostarch.com/crackingcodes/>).

The Program in Action

When you run `caesarcipher.py`, the output will look like this:

```
Caesar Cipher, by Al Sweigart al@inventwithpython.com
Do you want to (e)ncrypt or (d)ecrypt?
> e
Please enter the key (0 to 25) to use.
> 4
Enter the message to encrypt.
> Meet me by the rose bushes tonight.
QIIX QI FC XLI VSWI FYWLIW XSRMKLX.
Full encrypted text copied to clipboard.
```

```
Caesar Cipher, by Al Sweigart al@inventwithpython.com
Do you want to (e)ncrypt or (d)ecrypt?
> d
Please enter the key (0 to 26) to use.
> 4
Enter the message to decrypt.
> QIIX QI FC XLI VSWI FYWLIW XSRMKLX.
MEET ME BY THE ROSE BUSHES TONIGHT.
Full decrypted text copied to clipboard.
```

How It Works

Like most cipher programs, the Caesar cipher works by translating characters into numbers, performing some math operations on those numbers, and translating the numbers back into text characters. In the context of ciphers, we call these text characters *symbols*. Symbols can include letters, numeric digits, and punctuation marks, each of which gets assigned a unique integer. In the case of the Caesar cipher program, the symbols are all letters, and their integers are their position in the `SYMBOLS` string: `'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

```

25. while True: # Keep asking until the user enters e or d.
26.     print('Do you want to (e)ncrypt or (d)ecrypt?')
27.     response = input('> ').lower()
28.     if response.startswith('e'):
29.         mode = 'encrypt'
30.         break
31.     elif response.startswith('d'):
32.         mode = 'decrypt'
33.         break
34.     print('Please enter the letter e or d.')
35.
36. # Let the user enter the key to use:
37. while True: # Keep asking until the user enters a valid key.
38.     maxKey = len(SYMBOLS) - 1
39.     print('Please enter the key (0 to {}) to use.'.format(maxKey))
40.     response = input('> ').upper()
41.     if not response.isdecimal():
42.         continue
43.
44.     if 0 <= int(response) < len(SYMBOLS):
45.         key = int(response)
46.         break
47.
48. # Let the user enter the message to encrypt/decrypt:
49. print('Enter the message to {}'.format(mode))
50. message = input('> ')
51.
52. # Caesar cipher only works on uppercase letters:
53. message = message.upper()
54.
55. # Stores the encrypted/decrypted form of the message:
56. translated = ''
57.
58. # Encrypt/decrypt each symbol in the message:
59. for symbol in message:
60.     if symbol in SYMBOLS:
61.         # Get the encrypted (or decrypted) number for this symbol.
62.         num = SYMBOLS.find(symbol) # Get the number of the symbol.
63.         if mode == 'encrypt':
64.             num = num + key
65.         elif mode == 'decrypt':
66.             num = num - key

```

```

67.
68.         # Handle the wrap-around if num is larger than the length of
69.         # SYMBOLS or less than 0:
70.         if num >= len(SYMBOLS):
71.             num = num - len(SYMBOLS)
72.         elif num < 0:
73.             num = num + len(SYMBOLS)
74.
75.         # Add encrypted/decrypted number's symbol to translated:
76.         translated = translated + SYMBOLS[num]
77.     else:
78.         # Just add the symbol without encrypting/decrypting:
79.         translated = translated + symbol
80.
81. # Display the encrypted/decrypted string to the screen:
82. print(translated)
83.
84. try:
85.     pyperclip.copy(translated)
86.     print('Full {}ed text copied to clipboard.'.format(mode))
87. except:
88.     pass # Do nothing if pyperclip wasn't installed.

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. You can expand the encryptable symbols by adding characters to the SYMBOLS string.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `SYMBOLS = 'ABCDEFGHIJKLMNOPQRSTUVWXYZ'` on line 16 to `SYMBOLS = 'ABC'`?
2. What happens when you encrypt a message with key 0?
3. What error message do you get if you delete or comment out `translated = ''` on line 56?
4. What error message do you get if you delete or comment out `key = int(response)` on line 45?
5. What happens if you change `translated = translated + SYMBOLS[num]` on line 76 to `translated = translated + symbol`?

#7

CAESAR HACKER

This program can hack messages encrypted with the Caesar cipher from Project 6, even if you don't know the key. There are only 26 possible keys for the Caesar cipher, so a computer can easily try all possible decryptions and display the results to the user. In cryptography, we call this technique a *brute-force attack*. If you'd like to learn more about ciphers and code breaking, you can read my book *Cracking Codes with Python* (No Starch Press, 2018; <https://nostarch.com/crackingcodes/>).

The Program in Action

When you run *caesarhacker.py*, the output will look like this:

```
Caesar Cipher Hacker, by Al Sweigart al@inventwithpython.com
Enter the encrypted Caesar cipher message to hack.
> QIIX QI FC XLI VSWI FYWLIW XSRMKLX.
Key #0: QIIX QI FC XLI VSWI FYWLIW XSRMKLX.
Key #1: PHHW PH EB WKH URVH EXVKHV WRQLJKW.
Key #2: OGGV OG DA VJG TQUG DWUJGU VQPKIJV.
Key #3: NFFU NF CZ UIF SPTF CVTIFT UPOJHIU.
Key #4: MEET ME BY THE ROSE BUSHES TONIGHT.
Key #5: LDDS LD AX SGD QNRD ATRGDR SNMHFGS.
Key #6: KCCR KC ZW RFC PMQC ZSQFCQ RMLGEFR.
--snip--
```

How It Works

Note that lines 20 to 36 in this program are nearly identical to lines 55 to 78 in the Caesar cipher program. The hacking program implements the same decryption code, except that it does so in a for loop, which runs the code for every possible key.

Unfortunately, the hacking program isn't sophisticated enough to identify when it has found the correct key. It relies on a human to read the output and identify which decryption produced the original English (or whichever written language was encrypted). Chapter 11 of the book *Cracking Codes with Python* (No Starch Press, 2018) details how you can write Python code to detect English messages.

```
1. """Caesar Cipher Hacker, by Al Sweigart al@inventwithpython.com
2. This program hacks messages encrypted with the Caesar cipher by doing
3. a brute force attack against every possible key.
4. More info at:
5. https://en.wikipedia.org/wiki/Caesar_cipher#Breaking_the_cipher
6. View this code at https://nostarch.com/big-book-small-python-projects
7. Tags: tiny, beginner, cryptography, math"""
8.
9. print('Caesar Cipher Hacker, by Al Sweigart al@inventwithpython.com')
10.
11. # Let the user specify the message to hack:
12. print('Enter the encrypted Caesar cipher message to hack.')
13. message = input('> ')
14.
15. # Every possible symbol that can be encrypted/decrypted:
16. # (This must match the SYMBOLS used when encrypting the message.)
17. SYMBOLS = 'ABCDEFGHIJKLMNOPQRSTUVWXYZ'
18.
19. for key in range(len(SYMBOLS)): # Loop through every possible key.
20.     translated = ''
21.
22.     # Decrypt each symbol in the message:
23.     for symbol in message:
```

```
24.         if symbol in SYMBOLS:
25.             num = SYMBOLS.find(symbol) # Get the number of the symbol.
26.             num = num - key # Decrypt the number.
27.
28.             # Handle the wrap-around if num is less than 0:
29.             if num < 0:
30.                 num = num + len(SYMBOLS)
31.
32.             # Add decrypted number's symbol to translated:
33.             translated = translated + SYMBOLS[num]
34.         else:
35.             # Just add the symbol without decrypting:
36.             translated = translated + symbol
37.
38.     # Display the key being tested, along with its decrypted text:
39.     print('Key #{}: {}'.format(key, translated))
```

After entering the source code and running it a few times, try making experimental changes to it. Keep in mind that the string stored in the `SYMBOLS` variable must match the `SYMBOLS` variable in the Caesar cipher program that produced the encrypted text.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What error message do you get if you delete or comment out `translated = ''` on line 20?
2. What happens if you change `translated = translated + SYMBOLS[num]` on line 33 to `translated = translated + symbol`?
3. What happens if you enter an unencrypted message into the Caesar cipher hacker program?

#8

CALENDAR MAKER

This program generates printable text files of monthly calendars for the month and year you enter. Dates and calendars are a tricky topic in programming because there are so many different rules for determining the number of days in a month, which years are leap years, and which day of the week a particular date falls on. Fortunately, Python's `datetime` module handles these details for you. This program focuses on generating the multiline string for the monthly calendar page.

The Program in Action

When you run *calendarmaker.py*, the output will look like this:

```
Calendar Maker, by Al Sweigart al@inventwithpython.com
Enter the year for the calendar:
> 2029
Enter the month for the calendar, 1-12:
> 12
                                December 2029
...Sunday....Monday....Tuesday...Wednesday...Thursday....Friday....Saturday..
+-----+-----+-----+-----+-----+-----+-----+

Saved to calendar_2029_12.txt
```

How It Works

Note that the `getCalendarFor()` function returns a giant multiline string of the calendar for the given month and year. In this function, the `calText` variable stores this string, which adds the lines, spaces, and dates to it. To track the date, the `currentDate` variable holds a `datetime.date()` object, which gets

set to the next or previous date by adding or subtracting datetime .timedelta() objects. You can learn about Python's date and time modules by reading Chapter 17 of *Automate the Boring Stuff with Python* at <https://automatetheboringstuff.com/2e/chapter17/>.

```

After you've entered the code and run it a few times, try re-creating this program from scratch without looking at the source code in this book. It doesn't have to be exactly the same as this program; you can invent your own version! On your own, you can also try to figure out how to do the following:

- Add text inside some of the boxes for holidays.
- Add text inside some of the boxes for reoccurring events.
- Print a “mini” calendar that has dates without boxes.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. How can you make the calendar display abbreviated months? For example, show 'Jan' instead of 'January'?
2. What error message do you get if you delete or comment out `year = int(response)` on line 21?
3. How can you make the calendar not display the days of the week at the top?
4. How can you make the program not save the calendar to a file?
5. What happens if you delete or comment out `print(calText)` on line 93?

#9

CARROT IN A BOX

This is a simple and silly bluffing game for two human players. Each player has a box. One box has a carrot in it, and each player wants to have the carrot. The first player looks in their box and then tells the second player they either do or don't have the carrot. The second player gets to decide whether to swap boxes or not.

The ASCII art in the code makes typing this program take a while (though copying and pasting the ASCII art can speed up the task), but this project is good for beginners because it is straightforward, with minimal looping and no defined functions.

The Program in Action

When you run `carrotinabox.py`, the output will look like this:

```
Carrot in a Box, by Al Sweigart al@inventwithpython.com
--snip--
Human player 1, enter your name: Alice
Human player 2, enter your name: Bob
HERE ARE TWO BOXES:

/_____/ /_____/
+-----+ | +-----+ |
|   RED   | | |   GOLD  | | |
|   BOX   | | |   BOX   | | |
+-----+ / | +-----+ / |
        Alice        Bob
```

```
Alice, you have a RED box in front of you.
Bob, you have a GOLD box in front of you.
Press Enter to continue...
--snip--
When Bob has closed their eyes, press Enter...
Alice here is the inside of your box:
```

```
      WV
     |V|
     |V|
     | |
 /_____/ | /_____/
+-----+ | +-----+ |
|   RED   | | |   GOLD  | | |
|   BOX   | | |   BOX   | | |
+-----+ / | +-----+ / |
(carrot!)
   Alice        Bob
Press Enter to continue...
--snip--
```

How It Works

This program relies on the second player closing their eyes so they don't see the contents of the first player's box. In order to keep the second player from seeing the box contents after this step, we need to find a way to clear the screen. Line 83 does this with `print('\n' * 100)`. This prints 100 newline characters, causing the previously printed content to scroll up and out of view. This keeps the second player from accidentally seeing what was only intended for the first player. While the second player could always scroll up to see this text, it'd be obvious to the first player, who's sitting right next to them, that they had done so.

On lines 114, 130, and 142, the spacing of the vertical lines may look incorrect, but the program replaces the curly braces with the string `'RED '`

(with a space at the end) or 'GOLD'. The four characters in these strings will cause the rest of the box's vertical lines to line up with the rest of the ASCII-art image.

151. else:
152.     print(p2Name + ' is the winner!')
153.
154. print('Thanks for playing!')

```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Change the ASCII art for the boxes and carrots to something more ornate.
- Add a “would you like to play again?” feature that lets the players play again while keeping score.
- Add a third player that the second player must bluff to.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. Note that line 26 has the code `p1Name[:11]` and `p2Name[:11]`. Enter a name longer than 11 letters. What do you notice about how the program displays this name?
2. What happens if you omit the space at the end of `firstBox = 'RED '` on line 103?
3. What happens if you delete or comment out `print('\n' * 100)` on line 83?
4. What happens if you delete or comment out the `else:` on line 100 and `break` on line 101?

#10

CHO-HAN

Cho-han is a dice game played in gambling houses of feudal Japan. Two six-sided dice are rolled in a cup, and gamblers must guess if the sum is even (cho) or odd (han). The house takes a small cut of all winnings. The simple random number generation and basic math used to determine odd or even sums make this project especially suitable for beginners. More information about Cho-han can be found at <https://en.wikipedia.org/wiki/Cho-han>.

The Program in Action

When you run *chohan.py*, the output will look like this:

```
Cho-Han, by Al Sweigart al@inventwithpython.com
```

```
In this traditional Japanese dice game, two dice are rolled in a bamboo cup by the dealer sitting on the floor. The player must guess if the dice total to an even (cho) or odd (han) number.
```

```
You have 5000 mon. How much do you bet? (or QUIT)
```

```
> 400
```

```
The dealer swirls the cup and you hear the rattle of dice.
```

```
The dealer slams the cup on the floor, still covering the dice and asks for your bet.
```

```
    CHO (even) or HAN (odd)?
```

```
> cho
```

```
The dealer lifts the cup to reveal:
```

```
    GO - GO
```

```
    5 - 5
```

```
You won! You take 800 mon.
```

```
The house collects a 40 mon fee.
```

```
--snip--
```

How It Works

The `random.randint(1, 6)` call returns a random integer between 1 and 6, making it ideal for representing a six-sided die roll. However, we also need to display the Japanese words for the numbers one to six. Instead of having an `if` statement followed by five `elif` statements, we have a dictionary, stored in `JAPANESE_NUMBERS`, that maps the integers 1 to 6 to strings of the Japanese words. This is how line 57's `JAPANESE_NUMBERS[dice1]` and `JAPANESE_NUMBERS[dice2]` can display the Japanese words for the dice results in just one line of code.

63.         correctBet = 'CHO'
64.     else:
65.         correctBet = 'HAN'
66.
67.     playerWon = bet == correctBet
68.
69.     # Display the bet results:
70.     if playerWon:
71.         print('You won! You take', pot, 'mon.')
72.         purse = purse + pot # Add the pot from player's purse.
73.         print('The house collects a', pot // 10, 'mon fee.')

```

```
74.         purse = purse - (pot // 10) # The house fee is 10%.
75.     else:
76.         purse = purse - pot # Subtract the pot from player's purse.
77.         print('You lost!')
78.
79.     # Check if the player has run out of money:
80.     if purse == 0:
81.         print('You have run out of money!')
82.         print('Thanks for playing!')
83.         sys.exit()
```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Implement one of the variations of this game, described in the Wikipedia article, where multiple players bet against each other. Add computer-controlled gamblers with their own purses to play against.
- Add extra bonuses for certain rolls, such as 7 or snake eyes.
- Allow the player to bet on a specific number to get a bonus to their wager.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. How can you make the player start with a different amount of money?
2. How does the program prevent the player from betting more money than they have?
3. How does the program know if the sum of the two dice is even or odd?
4. What happens if you change `random.randint(1, 6)` on line 37 to `random.randint(1, 1)`?
5. Does the house still collect a 10 percent fee if you change `pot // 10` on line 73 (not line 74) to 0?
6. What happens if you delete or comment out lines 80, 81, 82, and 83?

#11

CLICKBAIT HEADLINE GENERATOR

Our website needs to trick people into looking at advertisements! But coming up with creative, original content is too hard.

Luckily, with the clickbait headline generator, we can make a computer come up with millions of outrageous fake headlines. They're all low quality, but readers don't seem to mind. This program generates as many headlines as you need from a Mad Libs-style template.

There's a lot of text in this program for the headline templates, but the code itself is straightforward and suitable for beginners.

The Program in Action

When you run `clickbait.py`, the output will look like this:

Clickbait Headline Generator

By Al Sweigart `al@inventwithpython.com`

Our website needs to trick people into looking at ads!

Enter the number of clickbait headlines to generate:

> **1000**

Big Companies Hate Him! See How This New York Cat Invented a Cheaper Robot

What Telephone Psychics Don't Want You To Know About Avocados

You Won't Believe What This North Carolina Shovel Found in Her Workplace

--snip--

14 Reasons Why Parents Are More Interesting Than You Think (Number 1 Will Surprise You!)

What Robots Don't Want You To Know About Cats

This Florida Telephone Psychic Didn't Think Robots Would Take Her Job. She Was Wrong.

How It Works

This program has several functions for generating different kinds of clickbait headlines. Each of them gets random words from `STATES`, `NOUNS`, `PLACES`, `WHEN`, and other lists. The functions then insert these words into a template string with the `format()` string method before returning this string. This is like a “Mad Libs” activity book, except the computer fills in the blanks, allowing the program to generate thousands of clickbait headlines in seconds.

- Add additional types of clickbait headlines.
- Add new categories of words, beyond NOUNS, STATES, and so on.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What error message do you get if you delete or comment out `numberOfHeadlines = int(response)` on line 34?
2. What error message do you get if you change `int(response)` to `response` on line 34?
3. What error message do you get if you change line 19 to `WHEN = []`?

#12

COLLATZ SEQUENCE

The Collatz sequence, also called the $3n + 1$ problem, is the simplest impossible math problem. (But don't worry, the program itself is easy enough for beginners.) From a starting number, n , follow three rules to get the next number in the sequence:

1. If n is even, the next number n is $n / 2$.
2. If n is odd, the next number n is $n * 3 + 1$.
3. If n is 1, stop. Otherwise, repeat.

It is generally thought, but so far not mathematically proven, that every starting number eventually terminates at 1. More information about the Collatz sequence can be found at https://en.wikipedia.org/wiki/Collatz_conjecture.

The Program in Action

When you run `collatz.py`, the output will look like this:

```
Collatz Sequence, or, the 3n + 1 Problem
By Al Sweigart al@inventwithpython.com
```

```
The Collatz sequence is a sequence of numbers produced from a starting
number n, following three rules:
```

```
--snip--
```

```
Enter a starting number (greater than 0) or QUIT:
```

```
> 26
```

```
26, 13, 40, 20, 10, 5, 16, 8, 4, 2, 1
```

```

16, 8, 4, 2, 1
```

How It Works

The `%` mod operator can help you determine if a number is even or odd. Remember that this operator is a sort of “remainder” operator. While 23 divided by 7 is 3-remainder-2, `23 mod 7` is simply 2. Even numbers divided by 2 have no remainder, while odd numbers divided by 2 have a remainder of 1. When `n` is even, the condition in `if n % 2 == 0`: on line 33 evaluates to `True`. When `n` is odd, it evaluates to `False`.

36.         n = 3 * n + 1
37.
38.     print(', ' + str(n), end='', flush=True)
39.     time.sleep(0.1)
40. print()
```

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. How many numbers are in a Collatz sequence that begins with 32?
2. How many numbers are in a Collatz sequence that begins with 33?
3. Are the Collatz sequences for starting numbers that are powers of two (2, 4, 8, 16, 32, 64, 128, on so on) always composed of only even numbers (aside from the final 1)?
4. What happens when you enter 0 for the starting integer?

#13

CONWAY'S GAME OF LIFE

Conway's Game of Life is a cellular automata simulation that follows simple rules to create interesting patterns. It was invented by mathematician John Conway in 1970 and popularized by Martin Gardner's "Mathematical Games" column in *Scientific American*. Today, it's a favorite among programmers and computer scientists, though it's more an interesting visualization than a true "game." The two-dimensional board has a grid of "cells," each of which follows three simple rules:

- Living cells with two or three neighbors stay alive in the next step of the simulation.
- Dead cells with exactly three neighbors become alive in the next step of the simulation.
- Any other cell dies or stays dead in the next step of the simulation.

The living or dead state of the cells in the next step of the simulation depends entirely on their current state. The cells don't "remember" any older states. There is a large body of research regarding the patterns that these simple rules produce. Tragically, Professor Conway passed away of complications from COVID-19 in April 2020. More information about Conway's Game of Life can be found at https://en.wikipedia.org/wiki/Conway%27s_Game_of_Life, and more information about Martin Gardner at https://en.wikipedia.org/wiki/Martin_Gardner.

The Program in Action

When you run `conwaysgameoflife.py`, the output will look like this:

```

      0           0           00      0 0
0    0  0  0  0           0           0 0000      0 00
00   0  0           0           0           0 0
00    0  0           00           00           00
00     00           0 0  0           00           00
           000       00  00           00           0 00
           000       00  00           0 000
           000       0 000
           000       0 000       00  0
           000       00  000       0000  0 0
           0  00       0 0  000       0 00 00 0  0  00
           0  0       0  0  000       0 00 0  0 000
           0           0000 00       00  0  00000 0
00          0           0 000       0 000       0000      0

```

How It Works

The state of the cells is stored in dictionaries in the `cells` and `nextCells` variables. Both dictionaries have `(x, y)` tuples for keys (where `x` and `y` are integers), `'0'` for living cells, and `' '` for dead cells. Lines 40 to 44 are set up to print a representation of these dictionaries onto the screen. The `cells` variable's dictionary represents the current state of the cells, while `nextCells` stores the dictionary for the cells in the next step in the simulation.

59.                 numNeighbors += 1 # Top-left neighbor is alive.
60.             if cells[(x, above)] == ALIVE:
61.                 numNeighbors += 1 # Top neighbor is alive.
62.             if cells[(right, above)] == ALIVE:
63.                 numNeighbors += 1 # Top-right neighbor is alive.
64.             if cells[(left, y)] == ALIVE:
65.                 numNeighbors += 1 # Left neighbor is alive.
66.             if cells[(right, y)] == ALIVE:
67.                 numNeighbors += 1 # Right neighbor is alive.
68.             if cells[(left, below)] == ALIVE:

```

```

69.         numNeighbors += 1 # Bottom-left neighbor is alive.
70.     if cells[(x, below)] == ALIVE:
71.         numNeighbors += 1 # Bottom neighbor is alive.
72.     if cells[(right, below)] == ALIVE:
73.         numNeighbors += 1 # Bottom-right neighbor is alive.
74.
75.     # Set cell based on Conway's Game of Life rules:
76.     if cells[(x, y)] == ALIVE and (numNeighbors == 2
77.         or numNeighbors == 3):
78.         # Living cells with 2 or 3 neighbors stay alive:
79.         nextCells[(x, y)] = ALIVE
80.     elif cells[(x, y)] == DEAD and numNeighbors == 3:
81.         # Dead cells with 3 neighbors become alive:
82.         nextCells[(x, y)] = ALIVE
83.     else:
84.         # Everything else dies or stays dead:
85.         nextCells[(x, y)] = DEAD
86.
87.     try:
88.         time.sleep(1) # Add a 1 second pause to reduce flickering.
89.     except KeyboardInterrupt:
90.         print("Conway's Game of Life")
91.         print('By Al Sweigart al@inventwithpython.com')
92.         sys.exit() # When Ctrl-C is pressed, end the program.

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Adjust the percentage of cells that start as living, instead of always using 50 percent.
- Add the ability to read in the initial state from a text file, so the user can edit the starting cell states manually.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens when you change `WIDTH = 79` on line 10 to `WIDTH = 7`?
2. What happens if you delete or comment out `print('\n' * 50)` on line 36?
3. What happens if you change `random.randint(0, 1)` on line 28 to `random.randint(0, 10)`?
4. What happens if you change `nextCells[(x, y)] = DEAD` on line 85 to `nextCells[(x, y)] = ALIVE`?

#14

COUNTDOWN

This program displays a digital timer that counts down to zero. Rather than render numeric characters directly, the *sevseg.py* module from Project 64, “Seven-Segment Display Module,” generates the drawings for each digit. You must create this file before the Countdown program can work. Then, set the countdown timer to any number of seconds, minutes, and hours you like. This program is similar to Project 19, “Digital Clock.”

The Program in Action

When you run *countdown.py*, the output will look like this:

```
|_| |_| * |_| |_| * |_|_|
|_| |_| * |_| |_| * |_|_|
```

Press Ctrl-C to quit.

How It Works

After running `import sevseg`, you can call the `sevseg.getSevSegStr()` function to get a multiline string of the seven segment digits. However, the Countdown program needs to display a colon made out of asterisks in between the hours, minutes, and seconds. This requires splitting up the three lines of the multiline strings for these digits into three separate strings with the `splitlines()` method.

```
1. """Countdown, by Al Sweigart al@inventwithpython.com
2. Show a countdown timer animation using a seven-segment display.
3. Press Ctrl-C to stop.
4. More info at https://en.wikipedia.org/wiki/Seven-segment\_display

8.
9. import sys, time
10. import sevseg # Imports our sevseg.py program.
11.
12. # (!) Change this to any number of seconds:
13. secondsLeft = 30
14.
15. try:
16.     while True: # Main program loop.
17.         # Clear the screen by printing several newlines:
18.         print('\n' * 60)
19.
20.         # Get the hours/minutes/seconds from secondsLeft:
21.         # For example: 7265 is 2 hours, 1 minute, 5 seconds.
22.         # So 7265 // 3600 is 2 hours:
23.         hours = str(secondsLeft // 3600)
24.         # And 7265 % 3600 is 65, and 65 // 60 is 1 minute:
25.         minutes = str((secondsLeft % 3600) // 60)
26.         # And 7265 % 60 is 5 seconds:
27.         seconds = str(secondsLeft % 60)
28.
29.         # Get the digit strings from the sevseg module:
30.         hDigits = sevseg.getSevSegStr(hours, 2)
31.         hTopRow, hMiddleRow, hBottomRow = hDigits.splitlines()
32.
33.         mDigits = sevseg.getSevSegStr(minutes, 2)
34.         mTopRow, mMiddleRow, mBottomRow = mDigits.splitlines()
```

```

35.
36.         sDigits = sevseg.getSevSegStr(seconds, 2)
37.         sTopRow, sMiddleRow, sBottomRow = sDigits.splitlines()
38.
39.         # Display the digits:
40.         print(hTopRow + '   ' + mTopRow + '   ' + sTopRow)
41.         print(hMiddleRow + ' * ' + mMiddleRow + ' * ' + sMiddleRow)
42.         print(hBottomRow + ' * ' + mBottomRow + ' * ' + sBottomRow)
43.
44.         if secondsLeft == 0:
45.             print()
46.             print('   * * * * BOOM * * * *')
47.             break
48.
49.         print()
50.         print('Press Ctrl-C to quit.')
51.
52.         time.sleep(1) # Insert a one-second pause.
53.         secondsLeft -= 1
54. except KeyboardInterrupt:
55.     print('Countdown, by Al Sweigart al@inventwithpython.com')
56.     sys.exit() # When Ctrl-C is pressed, end the program.)

```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Prompt the user to enter the starting countdown time.
- Let the user enter a message to display at the end of the countdown.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `secondsLeft = 30` on line 13 to `secondsLeft = 30.5`?
2. What happens if you change the 2 on lines 30, 33, and 36 to 1?
3. What happens if you change `time.sleep(1)` on line 52 to `time.sleep(0.1)`?
4. What happens if you change `secondsLeft -= 1` on line 53 to `secondsLeft -= 2`?
5. What happens if you delete or comment out `print('\n' * 60)` on line 18?
6. What error message do you get if you delete or comment out `import sevseg` on line 10?

DEEP CAVE

This program is an animation of a deep cave that descends forever into the earth. Although short, this program takes advantage of the scrolling nature of the computer screen to produce an interesting and unending visualization, proof that it doesn't take much code to produce something fun to watch. This program is similar to Project 58, "Rainbow."

```

24.
25.     # Check for Ctrl-C press during the brief pause:
26.     try:
27.         time.sleep(PAUSE_AMOUNT)
28.     except KeyboardInterrupt:
29.         sys.exit() # When Ctrl-C is pressed, end the program.
30.
31.     # Adjust the left side width:
32.     diceRoll = random.randint(1, 6)
33.     if diceRoll == 1 and leftWidth > 1:
34.         leftWidth = leftWidth - 1 # Decrease left side width.
35.     elif diceRoll == 2 and leftWidth + gapWidth < WIDTH - 1:
36.         leftWidth = leftWidth + 1 # Increase left side width.
37.     else:
38.         pass # Do nothing; no change in left side width.
39.
40.     # Adjust the gap width:
41.     # (!) Try uncommenting out all of the following code:
42.     #diceRoll = random.randint(1, 6)
43.     #if diceRoll == 1 and gapWidth > 1:
44.     #    gapWidth = gapWidth - 1 # Decrease gap width.
45.     #elif diceRoll == 2 and leftWidth + gapWidth < WIDTH - 1:
46.     #    gapWidth = gapWidth + 1 # Increase gap width.
47.     #else:
48.     #    pass # Do nothing; no change in gap width.

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change (' ' * gapWidth) on line 23 to ('.' * gapWidth)?
2. What happens if you change random.randint(1, 6) on line 32 to random.randint(1, 1)?
3. What happens if you change random.randint(1, 6) on line 32 to random.randint(2, 2)?
4. What error message do you get if you delete or comment out leftWidth = 20 on line 17?
5. What happens if you change WIDTH = 70 on line 10 to WIDTH = -70?
6. What error message do you get if you change PAUSE_AMOUNT = 0.05 on line 11 to PAUSE_AMOUNT = -0.05?

#16

DIAMONDS

This program features a small algorithm for drawing ASCII-art diamonds of various sizes. It contains functions for drawing either an outline or filled-in-style diamond of the size you dictate. These functions are good practice for a beginner; try to understand the pattern behind the diamond drawings as they increase in size.

The Program in Action

When you run *diamonds.py*, the output will look like this:

Diamonds, by Al Sweigart al@inventwithpython.com

```
^
v

^
v

^ \
v /
v \

^ \
// \
\\ /
v

^ \
/ \
\ /
v

^ \
/// \
\\\ /
\\ /
v
--snip--
```

How It Works

A helpful approach to creating this program yourself is to “draw” diamonds of several sizes in your editor first and then figure out the pattern they follow as the diamond gets bigger. This technique will help you realize that each row of an outline diamond has four parts: the number of leading spaces, the exterior forward slash, the number of interior spaces, and the exterior backslash. Filled diamonds have several interior forward slashes and backslashes rather than interior spaces. Cracking this pattern is how I wrote *diamonds.py*.

31.         print('\') # Right side of diamond.
32.
33.     # Display the bottom half of the diamond:
34.     for i in range(size):
35.         print(' ' * i, end='') # Left side space.
36.         print('\', end='') # Left side of diamond.
37.         print(' ' * ((size - i - 1) * 2), end='') # Interior of diamond.
38.         print('/') # Right side of diamond.
39.
40.
41. def displayFilledDiamond(size):
42.     # Display the top half of the diamond:
43.     for i in range(size):
44.         print(' ' * (size - i - 1), end='') # Left side space.
45.         print('/' * (i + 1), end='') # Left half of diamond.
46.         print('\\' * (i + 1)) # Right half of diamond.
47.
48.     # Display the bottom half of the diamond:
49.     for i in range(size):
50.         print(' ' * i, end='') # Left side space.
51.         print('\\' * (size - i), end='') # Left side of diamond.
52.         print('/' * (size - i)) # Right side of diamond.
53.
54.
55. # If this program was run (instead of imported), run the game:
56. if __name__ == '__main__':
57.     main()

```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Create other shapes: triangles, rectangles, and rhombuses.
- Output the shapes to a text file instead of the screen.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens when you change `print('\n')` on line 31 to `print('@')`?
2. What happens when you change `print(' ' * (i * 2), end='')` on line 30 to `print('@' * (i * 2), end='')`?
3. What happens when you change `range(0, 6)` on line 18 to `range(0, 30)`?
4. What happens when you delete or comment out `for i in range(size):` on line 34 or on line 49?

#17

DICE MATH

This math quiz program rolls two to six dice whose sides you must add up as quickly as possible. But this program operates as more than just automated flash cards; it draws the faces of the dice to random places on the screen. The ASCII-art aspect adds a fun twist while you practice arithmetic.

The Program in Action

When you run `dicemath.py`, the output will look like this:

Dice Math, by Al Sweigart `al@inventwithpython.com`

Add up the sides of all the dice displayed on the screen. You have 30 seconds to answer as many as possible. You get 4 points for each correct answer and lose 1 point for each incorrect answer.

Press Enter to begin...

```
+-----+
| 0  0 |
|  0   |
| 0  0 |
+-----+
```

```
+-----+
|      |
|      |
| 0     |
|      |
| 0     |
+-----+
```

```
+-----+
| 0  0 |
| 0  0 |
+-----+
+-----+
| 0     |
|      |
|      |
|      |
|      |
+-----+
```

Enter the sum: **13**

--snip--

How It Works

The dice on the screen are represented by a dictionary stored in the `canvas` variable. In Python, tuples are similar to lists, but their contents cannot be changed. The keys to this dictionary are `(x, y)` tuples marking the position of a die's top left corner, while the values are one of the "dice tuples" in `ALL_DICE`. You can see in lines 28 to 80 that each dice tuple contains a list of strings, which graphically represents one possible die face, and an integer of how many pips are on the die face. The program uses this information to display the dice and calculate their sum total.

Lines 174 to 177 render the data in the `canvas` dictionary on the screen in a manner similar to how Project 13, "Conway's Game of Life," renders cells on the screen.

192. print('Score:   ', score)

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Redesign the ASCII-art dice faces.
- Add dice faces with seven, eight, or nine pips.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change line 82 to `ALL_DICE = [D1]`?
2. What happens if you change `get((cx, cy), ' ')` on line 176 to `get((cx, cy), '.')`?
3. What happens if you change `correctAnswers += 1` on line 182 to `correctAnswers += 0`?
4. What error message do you get if you delete or comment out `correctAnswers = 0` on line 93?

#18

DICE ROLLER

Dungeons & Dragons and other tabletop role-playing games use special dice that can have 4, 8, 10, 12, or even 20 sides. These games also have a specific notation for indicating which dice to roll. For example, 3d6 means rolling three six-sided dice, while 1d10+2 means rolling one ten-sided die and adding a two-point bonus to the roll. This program simulates this dice rolling, in case you forgot to bring your own. It can also simulate rolling dice that don't physically exist, such as a 38-sided die.

The Program in Action

When you run *diceroller.py*, the output will look like this:

```
Dice Roller, by Al Sweigart al@inventwithpython.com
--snip--
> 3d6
7 (3, 2, 2)
> 1d10+2
9 (7, +2)
> 2d38-1
32 (20, 13, -1)
> 100d6
364 (3, 3, 2, 4, 2, 1, 4, 2, 4, 6, 4, 5, 4, 3, 3, 3, 2, 5, 1, 5, 6, 6, 6, 4,
5, 5, 1, 5, 2, 2, 2, 5, 1, 1, 2, 1, 4, 5, 6, 2, 4, 3, 4, 3, 5, 2, 2, 1, 1, 5,
1, 3, 6, 6, 6, 6, 5, 2, 6, 5, 4, 4, 5, 1, 6, 6, 6, 4, 2, 6, 2, 6, 2, 2, 4, 3,
6, 4, 6, 4, 2, 4, 3, 3, 1, 6, 3, 3, 4, 4, 5, 5, 5, 6, 2, 3, 6, 1, 1, 1)
--snip--
```

How It Works

Most of the code in this program is dedicated to ensuring that the input the user entered is properly formatted. The actual random dice rolls themselves are simple calls to `random.randint()`. This function has no bias: each integer in the range passed to it is equally likely to be returned. This makes `random.randint()` ideal for simulating dice rolls.

```
1. """Dice Roller, by Al Sweigart al@inventwithpython.com
2. Simulates dice rolls using the Dungeons & Dragons dice roll notation.
3. View this code at https://nostarch.com/big-book-small-python-projects
4. Tags: short, simulation"""
5.
6. import random, sys
7.
8. print('Dice Roller, by Al Sweigart al@inventwithpython.com')
9.
10. Enter what kind and how many dice to roll. The format is the number of
11. dice, followed by "d", followed by the number of sides the dice have.
12. You can also add a plus or minus adjustment.
13.
14. Examples:
15. 3d6 rolls three 6-sided dice
16. 1d10+2 rolls one 10-sided die, and adds 2
17. 2d38-1 rolls two 38-sided die, and subtracts 1
18. QUIT quits the program
19. '''
20.
21. while True: # Main program loop:
22.     try:
23.         diceStr = input('> ') # The prompt to enter the dice string.
24.         if diceStr.upper() == 'QUIT':
25.             print('Thanks for playing!')
26.             sys.exit()
```

```

27.
28.     # Clean up the dice string:
29.     diceStr = diceStr.lower().replace(' ', '')
30.
31.     # Find the "d" in the dice string input:
32.     dIndex = diceStr.find('d')
33.     if dIndex == -1:
34.         raise Exception('Missing the "d" character.')
35.
36.     # Get the number of dice. (The "3" in "3d6+1"):
37.     numberOfDice = diceStr[dIndex]
38.     if not numberOfDice.isdecimal():
39.         raise Exception('Missing the number of dice.')
40.     numberOfDice = int(numberOfDice)
41.
42.     # Find if there is a plus or minus sign for a modifier:
43.     modIndex = diceStr.find('+')
44.     if modIndex == -1:
45.         modIndex = diceStr.find('-')
46.
47.     # Find the number of sides. (The "6" in "3d6+1"):
48.     if modIndex == -1:
49.         numberOfSides = diceStr[dIndex + 1 :]
50.     else:
51.         numberOfSides = diceStr[dIndex + 1 : modIndex]
52.     if not numberOfSides.isdecimal():
53.         raise Exception('Missing the number of sides.')
54.     numberOfSides = int(numberOfSides)
55.
56.     # Find the modifier amount. (The "1" in "3d6+1"):
57.     if modIndex == -1:
58.         modAmount = 0
59.     else:
60.         modAmount = int(diceStr[modIndex + 1 :])
61.         if diceStr[modIndex] == '-':
62.             # Change the modification amount to negative:
63.             modAmount = -modAmount
64.
65.     # Simulate the dice rolls:
66.     rolls = []
67.     for i in range(numberOfDice):
68.         rollResult = random.randint(1, numberOfSides)
69.         rolls.append(rollResult)
70.
71.     # Display the total:
72.     print('Total:', sum(rolls) + modAmount, '(Each die:', end='')
73.
74.     # Display the individual rolls:
75.     for i, roll in enumerate(rolls):
76.         rolls[i] = str(roll)
77.     print(', '.join(rolls), end='')
78.
79.     # Display the modifier amount:
80.     if modAmount != 0:
81.         modSign = diceStr[modIndex]

```

```
82.         print(', {}'.format(modSign, abs(modAmount)), end='')
83.         print(')')
84.
85.     except Exception as exc:
86.         # Catch any exceptions and display the message to the user:
87.         print('Invalid input. Enter something like "3d6" or "1d10+2".')
88.         print('Input was invalid because: ' + str(exc))
89.         continue # Go back to the dice string prompt.
```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Add a multiplication modifier to complement the addition and subtraction modifier.
- Add the ability to automatically remove the lowest die roll.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you delete or comment out `rolls.append(rollResult)` on line 69?
2. What happens if you change `rolls.append(rollResult)` on line 69 to `rolls.append(-rollResult)`?
3. What happens if you delete or comment out `print(', '.join(rolls), end='')` on line 77?
4. What happens if instead of a dice roll you enter nothing?

#19

DIGITAL CLOCK

This program displays a digital clock with the current time. Rather than render numeric characters directly, the *seuseg.py* module from Project 64, “Seven-Segment Display Module,” generates the drawings for each digit. This program is similar to Project 14, “Countdown.”

The Program in Action

When you run *digitalclock.py*, the output will look like this:

```
|_| |_| * |_| |_| * |_| |_|
|_| |_| * |_| |_| * |_| |_|
```

Press Ctrl-C to quit.

How It Works

The digital clock program looks similar to Project 14, “Countdown.” Not only do they both import the *sevseg.py* module, but they must split up the multiline strings returned by *sevseg.getSevSegStr()* with the *splitlines()* method. This allows us to put a colon made of asterisks in between the digits for the hour, minute, and second sections of the clock. Compare this code with the code in Countdown to see how it is similar and how it is different.

```

40.         print()
41.         print('Press Ctrl-C to quit.')
42.
43.         # Keep looping until the second changes:
44.         while True:
45.             time.sleep(0.01)
46.             if time.localtime().tm_sec != currentTime.tm_sec:
47.                 break
48.     except KeyboardInterrupt:
49.         print('Digital Clock, by Al Sweigart al@inventwithpython.com')
50.         sys.exit() # When Ctrl-C is pressed, end the program.

```

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `time.sleep(0.01)` on line 45 to `time.sleep(2)`?
2. What happens if you change the 2 on lines 27, 30, and 33 to 1?
3. What happens if you delete or comment out `print('\n' * 60)` on line 15?
4. What error message do you get if you delete or comment out `import sevseg` on line 10?

#20

DIGITAL STREAM

This program mimics the “digital stream” visualization from the science fiction movie *The Matrix*. Random beads of binary “rain” stream up from the bottom of the screen, creating a cool, hacker-like visualization. (Unfortunately, due to the way text moves as the screen scrolls down, it’s not possible to make the streams fall downward without using a module such as `bext`.)

The Program in Action

When you run *digitalstream.py*, the output will look like this:

```
Digital Stream Screensaver, by Al Sweigart al@inventwithpython.com
Press Ctrl-C to quit.

      0          0
      0          0
1     0 0 1      1 0          1
0     0 0 1      0 0 0      0          0
0     1 0 0      0 1 0 0      1          0 1
0     1 0 0      1 0 1 1      1          0 1 0
0     1 0 0      0 0 0 1 1      0          0 1 1 0
1    1 0 1 0      1 1 1 0 1 0      1 0 1 0
      1 1 0 1 0      1 0 0 1 1 1      1 1 1 1
      0 1 0 1 0      1 1 0 0 1 1      0 1 0
1    1 0 0 1 1      0 1 1 1 0 0      1 0 0
      0 0 0 1 0      1 1 1 1 1 1      0 0
--snip--
```

How It Works

Like Project 15, “Deep Cave,” this program uses the scrolling caused by `print()` calls to create an animation. Each column is represented by an integer in the `columns` list: `columns[0]` is an integer for the leftmost column, `columns[1]` is an integer for the column to the right of that one, and so on. The program initially sets these integers to 0, meaning it prints ' ' (an empty space string) instead of a stream in that column. Randomly, it changes each integer to a value between `MIN_STREAM_LENGTH` and `MAX_STREAM_LENGTH`. That integer decreases by 1 each time a line is printed. As long as a column’s integer is greater than 0, the program prints a random 1 or 0 in that column. This produces the “digital stream” effect you see on the screen.

DNA VISUALIZATION

Deoxyribonucleic acid is a tiny molecule that exists in every cell of our bodies and contains the blueprint for how our bodies grow. It looks like a *double helix* (a sort of twisted ladder) of pairs of nucleotide molecules: guanine, cytosine, adenine, and thymine. These are represented by the letters G, C, A, and T. DNA is a long molecule; it's microscopic, but if it were stretched out, its 3 billion base pairs would be 2 meters long! This program is a simple animation of DNA.

The Program in Action

When you run *dna.py*, the output will look like this:

```
DNA Animation, by Al Sweigart al@inventwithpython.com
Press Ctrl-C to quit...
  #G-C#
  #C---G#
  #T-----A#
  #T-----A#
  #A-----T#
  #G----C#
  #G---C#
  #C-G#
  ##
  #T-A#
  #C---G#
  #G----C#
  #G----C#
  #T-----A#
  #A-----T#
  #C---G#
  #G-C#
  ##
  #T-A#
  #T---A#
  #A-----T#
--snip--
```

How It Works

Similar to Project 15, “Deep Cave,” and Project 20, “Digital Stream,” this program creates a scrolling animation by printing strings from the `ROWS` list. The AT and CG pairs are inserted into each string with the `format()` string method.

```

62.
63.         # Print the row.
64.         print(ROWS[rowIndex].format(leftNucleotide, rightNucleotide))
65.         time.sleep(PAUSE) # Add a slight pause.
66.     except KeyboardInterrupt:
67.         sys.exit() # When Ctrl-C is pressed, end the program.

```

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `rowIndex = rowIndex + 1` on line 42 to `rowIndex = rowIndex + 2`?
2. What happens if you change `random.randint(1, 4)` on line 53 to `random.randint(1, 2)`?
3. What error message do you get if you set `PAUSE = 0.15` on line 9 to `PAUSE = -0.15`?

#22

DUCKLINGS

This program creates a scrolling field of ducklings. Each duckling has slight variations: they can face left or right and have two different body sizes, four types of eyes, two types of mouths, and three positions for their wings. This gives us 96 different possible variations, which the Ducklings program produces endlessly.

The Program in Action

When you run *ducklings.py*, the output will look like this:

```
Duckling Screensaver, by Al Sweigart al@inventwithpython.com
Press Ctrl-C to quit...

=" )
( v)="
^ ^ ( v) >'')
    ^ ^ ( ^)
        ^ ^
>")
( v) =^^)
    ^ ^ ( >)
    ^ ^
("< ("< >") ^ ^ ( ^)
(^) (<) ( ^) ( ^)
^^ ^^ ( ^) ( ^)
    (^) ( ^) ( ^)
    (v ) ("< ( ^) ( ^)
    ^^    ^ ^ ^ ^
--snip--
```

How It Works

This program represents ducklings with a `Duckling` class. The random features of each duckling are chosen in the `__init__()` method of this class, while the various body parts of each duckling are returned by the `getHeadStr()`, `getBodyStr()`, and `getFeetStr()` methods.

```

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `random.choice([LEFT, RIGHT])` on line 75 to `random.choice([LEFT])`?
2. What happens if you change `self.partToDisplayNext = BODY` on line 194 to `self.partToDisplayNext = None`?
3. What happens if you change `self.partToDisplayNext = FEET` on line 197 to `self.partToDisplayNext = BODY`?
4. What happens if you change `return self.getHeadStr()` on line 195 to `return self.getFeetStr()`?

#23

ETCHING DRAWER

When you move a pen point around the screen with the WASD keys, the etching drawer forms a picture by tracing a continuous line, like the Etch A Sketch toy. Let your artistic side break out and see what images you can create! This program also lets you save your drawings to a text file so you can print them out later. Plus, you can copy and paste the WASD movements of other drawings into this program, like the WASD commands for the Hilbert Curve fractal presented on lines 6 to 14 of the source code.

The Program in Action

When you run *etchingdrawer.py*, the output will look like Figure 23-1.

Figure 23-1: A drawing made in the etching drawer program

How It Works

Like Project 17, “Dice Math,” this program uses a dictionary stored in a variable named *canvas* to record the lines of the drawing. The keys are (x, y) tuples and the values are strings representing the line shape to draw at those x, y coordinates on the screen. A full list of Unicode characters you can use in your Python programs is given in Appendix B.

Line 126 has a function call to `open()` that passes an `encoding='utf-8'` argument. The reasons are beyond the scope of this book, but this is necessary for Windows to write the line characters to a text file.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `response = input('> ').upper()` on line 101 to `response = input('> ')`?
2. What happens if you change `canvasStr += '#'` on line 61 to `canvasStr += '@'`?
3. What happens if you change `canvasStr += ' '` on line 89 to `canvasStr += '.'`?
4. What happens if you change `moves = []` on line 94 to `moves = list('SDWDDSASDSA AWASSDSAS')`?

#24

FACTOR FINDER

A number's factors are any two other numbers that, when multiplied with each other, produce the number. For example, $2 \times 13 = 26$, so 2 and 13 are factors of 26. Also, $1 \times 26 = 26$, so 1 and 26 are also factors of 26. Therefore, we say that 26 has four factors: 1, 2, 13, and 26.

If a number only has two factors (1 and itself), we call that a prime number. Otherwise, we call it a composite number. Use the factor finder to discover some new prime numbers! (Hint: Prime numbers always end with an odd number that isn't 5.) You can also have the computer calculate them with Project 56, "Prime Numbers."

The math for this program isn't too heavy, making it an ideal project for beginners.

The Program in Action

When you run *factorfinder.py*, the output will look like this:

```
Factor Finder, by Al Sweigart al@inventwithpython.com
--snip--
Enter a number to factor (or "QUIT" to quit):
> 26
1, 2, 13, 26
Enter a number to factor (or "QUIT" to quit):

4352784
Enter a number to factor (or "QUIT" to quit):
> 9787
1, 9787
Enter a number to factor (or "QUIT" to quit):
> quit
```

How It Works

We can tell if a number is a factor of another number by checking if the second number evenly divides the first number. For example, 7 is a factor of 21 because $21 \div 7$ is 3. This also gives us another of 21's factors: 3. However, 8 is not a factor of 21 because $21 \div 8 = 2.625$. The fractional remainder component tells us this equation did not divide evenly.

The % mod operator will perform division and tell us if there's a remainder: $21 \% 7$ evaluates to 0, meaning there is no remainder and 7 is a factor of 21, whereas $21 \% 8$ evaluates to 1, a nonzero value, meaning that it isn't a factor. The factor finder program uses this technique on line 35 to determine which numbers are factors.

The `math.sqrt()` function returns the square root of the number passed to it. For example, `math.sqrt(25)` returns 5.0 because 5 times itself is 25, making it the square root of 25.

#25

FAST DRAW

This program tests your reaction speed: press ENTER as soon as you see the word DRAW. But careful, though. Press it before DRAW appears, and you lose. Are you the fastest keyboard in the west?

The Program in Action

When you run *fastdraw.py*, the output will look like this:

```
Fast Draw, by Al Sweigart al@inventwithpython.com
```

```
Time to test your reflexes and see if you are the fastest  
draw in the west!
```

```
When you see "DRAW", you have 0.3 seconds to press Enter.  
But you lose if you press Enter before "DRAW" appears.
```

```
Press Enter to begin...
```

```
It is high noon...
```

```
DRAW!
```

```
You took 0.3485 seconds to draw. Too slow!  
Enter QUIT to stop, or press Enter to play again.
```

```
> quit  
Thanks for playing!
```

How It Works

The `input()` function pauses the program while waiting for the user to enter a string. This simple behavior means that we can't create real-time games with just `input()`. However, your programs will *buffer* keyboard input, meaning that if you pressed the C, A, and T keys before `input()` is called, those characters will be saved, and they'll appear immediately once `input()` executes.

By recording the time just before the `input()` call on line 22 and the time just after the `input()` call on line 24, we can determine how long the player took to press ENTER. However, if they pressed ENTER before `input()` was called, the buffered ENTER press causes `input()` to return immediately (usually in about 3 milliseconds). This is why line 26 checks if the time was less than 0.01 seconds, or 10 milliseconds, to determine that the player pressed ENTER too soon.

4. What happens if you delete or comment out `input('Press Enter to begin...')` on line 15?

#26

FIBONACCI

The Fibonacci sequence is a famous mathematical pattern credited to Italian mathematician Fibonacci in the 13th century (though others had discovered it even earlier).

The sequence begins with 0 and 1, and the next number is always the sum of the previous two numbers.

The sequence continues forever:

0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987 . . .

The Fibonacci sequence has applications in music composition, stock market prediction, the pattern of florets in the head of sunflowers, and many other areas. This program lets you calculate the sequence as high as you are willing to go. More information about the Fibonacci sequence can be found at https://en.wikipedia.org/wiki/Fibonacci_number.

The Program in Action

When you run *fibonacci.py*, the output will look like this:

```
Fibonacci Sequence, by Al Sweigart al@inventwithpython.com
--snip--
Enter the Nth Fibonacci number you wish to
calculate (such as 5, 50, 1000, 9999), or QUIT to quit:
> 50

0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987, 1597, 2584,
4181, 6765, 10946, 17711, 28657, 46368, 75025, 121393, 196418, 317811, 514229,
832040, 1346269, 2178309, 3524578, 5702887, 9227465, 14930352, 24157817,
39088169, 63245986, 102334155, 165580141, 267914296, 433494437, 701408733,
1134903170, 1836311903, 2971215073, 4807526976, 7778742049
```

How It Works

Because Fibonacci numbers quickly become very large, lines 46 to 50 check if the user has entered a number that's 10,000 or larger and displays a warning that it may take some time for the output to finish displaying on the screen. While your programs can quickly do millions of calculations almost instantly, printing text to the screen is relatively slow and could take several seconds. The warning in our program reminds the user they can always terminate the program by pressing CTRL-C.

37.     print('The #1 Fibonacci number is 0.')
38.     continue
39. elif nth == 2:
40.     print('0, 1')
41.     print()
42.     print('The #2 Fibonacci number is 1.')
43.     continue
44.
45. # Display warning if the user entered a large number:
46. if nth >= 10000:
47.     print('WARNING: This will take a while to display on the')
48.     print('screen. If you want to quit this program before it is')
49.     print('done, press Ctrl-C.')
50.     input('Press Enter to begin...')
51.
52. # Calculate the Nth Fibonacci number:
53. secondToLastNumber = 0
54. lastNumber = 1
55. fibNumbersCalculated = 2
56. print('0, 1, ', end='') # Display the first two Fibonacci numbers.
57.
58. # Display all the later numbers of the Fibonacci sequence:
59. while True:
60.     nextNumber = secondToLastNumber + lastNumber
61.     fibNumbersCalculated += 1
62.
63.     # Display the next number in the sequence:
64.     print(nextNumber, end='')
65.
66.     # Check if we've found the Nth number the user wants:
67.     if fibNumbersCalculated == nth:
68.         print()
69.         print()
70.         print('The #', fibNumbersCalculated, ' Fibonacci ',
71.               'number is ', nextNumber, sep='')
72.         break
73.
74.     # Print a comma in between the sequence numbers:
75.     print(', ', end='')
76.
77.     # Shift the last two numbers:
78.     secondToLastNumber = lastNumber
79.     lastNumber = nextNumber

```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Use different starting numbers than 0 and 1.
- Create the next number by adding the previous three numbers instead of the previous two.

Exploring the Program

This is a base program, so there aren't many options to customize it. Instead, consider: how could you use this program? What other useful sequences could be programmed?

#27

FISH TANK

Watch your own virtual fish in a virtual fish tank, complete with air bubblers and kelp plants. Each time you run the program, it randomly generates the fish using different fish types and colors. Take a break and enjoy the calm serenity of this software aquarium, or try programming in some virtual sharks to terrorize its inhabitants! You can't run this program from your IDE or editor. This program uses the `bext` module and must be run from the Command Prompt or Terminal in order to display correctly. More information about the `bext` module can be found at <https://pypi.org/project/bext/>.

The Program in Action

Figure 27-1 show what the output will look like when you run *fishtank.py*.

```

C:\WINDOWS\system32\cmd.exe - py fishtank.py
Fish Tank, by Al Sweigart Ctrl-C to quit.

```

Figure 27-1: The output of the fish tank program, with several fish, kelp plants, and bubbles

How It Works

Modern graphical programs often generate animations by erasing their entire window and redrawing it 30 or 60 times a second. This gives them a *frame rate* of 30 or 60 frames per second (FPS). The higher the FPS, the more fluid the animated movement appears.

Drawing to terminal windows is much slower. If we erased the entire terminal window to redraw its contents with the `text` module, we typically would only get about 3 or 4 FPS. This would cause a noticeable flicker in the window.

We can speed this up by only drawing characters to the parts of the terminal window that have changed. Most of the fish tank program's output is empty space, so to make the elements move, the `clearAquarium()` only has to draw ' ' space characters to the places where the fish, kelp, and bubbles currently are. This increases our frame rate, reduces flickering, and makes for a much more pleasant fish tank animation.

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Add crabs that move along on the sandy bottom.
- Add an ASCII-art castle that appears randomly on the sandy bottom.
- Make the fish randomly increase their speed for a short burst.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `LONGEST_FISH_LENGTH = 10` on line 51 to `LONGEST_FISH_LENGTH = 50`?
2. What happens if you change `'right': fishType['right']` on line 121 to `'right': fishType['left']`?
3. What happens if you change `bext.fg('green')` on line 249 to `bext.fg('red')`?
4. What happens if you delete or comment out `clearAquarium()` on line 92?
5. What happens if you change `bext.fg(fish['colors'][i])` on line 245 to `bext.fg('random')`?
6. What happens if you change `random.randint(10, 60)` on line 161 to 1?

#28

FLOODER

Flooder is a colorful game where a player tries to fill the board with a single color by changing the color of the tile in the upper-left corner. This new color spreads to all neighboring tiles that matched the original color. It's similar to the Flood It mobile game. This program also has a colorblind mode, which uses shapes instead of flat colored tiles. It relies on the recursive flood fill algorithm to paint the board and works similarly to the “paint bucket” or “fill” tool in many painting applications.

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Add additional shapes and colors.
- Create other board shapes besides a rectangle.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What error message do you get if you change `board = {}` on line 92 to `board = []`?
2. What error message do you get if you change `return board` on line 105 to `return None`?
3. What happens if you change `movesLeft -= 1` on line 76 to `movesLeft -= 0`?

#29

FOREST FIRE SIM

This simulation shows a forest whose trees are constantly growing and then being burned down. On each step of the simulation, there is a 1 percent chance that a blank space grows into a tree and a 1 percent chance that a tree is struck by lightning and burns. Fires will spread to adjacent trees, so a densely packed forest is more likely to suffer a larger fire than a sparsely packed one. This simulation was inspired by Nicky Case's Emoji Sim at <http://ncase.me/simulating/model/>.

The Program in Action

When you run `forestfiresim.py`, the output will look like this:

```
C:\WINDOWS\system32\cmd.exe - py forestfiresim.py
      A A A      A A A      W      A A A A      AA      A AA
    A A A      WW      A A A      WA W A      W A      AA A A      A      A A
  A      A      A      A      A      AA      A W      A A A      AA      A

Grow chance: 1.0% Lightning chance: 1.0% Press Ctrl-C to quit.
```

Figure 29-1: The forest fire simulation, with green As for trees and red Ws for flames

How It Works

This simulation is an example of *emergent behavior*—the interaction between simple parts in a system creating complicated patterns. Empty spaces grow into trees, lightning turns trees into fire, and fire turns trees back into empty spaces while spreading to neighboring trees. By adjusting the tree growth and lightning strike rate, you can cause the forest to display different phenomena. For example, a low lightning chance but high growth rate causes large, constant forest fires, since the trees tend to be near each other and quickly replenish. A low growth rate but high lightning strike chance creates several small fires that quickly extinguish due to a lack of nearby trees. We don't explicitly program any of this behavior; rather, it naturally emerges from the system that we created.

91.     """Display the forest data structure on the screen."""
92.     bext.goto(0, 0)
93.     for y in range(forest['height']):
94.         for x in range(forest['width']):
95.             if forest[(x, y)] == TREE:
96.                 bext.fg('green')
97.                 print(TREE, end='')
98.             elif forest[(x, y)] == FIRE:
99.                 bext.fg('red')
100.                print(FIRE, end='')
101.            elif forest[(x, y)] == EMPTY:
102.                print(EMPTY, end='')
103.        print()
104.        bext.fg('reset') # Use the default font color.
105.        print('Grow chance: {}% '.format(GROW_CHANCE * 100), end='')
106.        print('Lightning chance: {}% '.format(FIRE_CHANCE * 100), end='')
107.        print('Press Ctrl-C to quit.')
108.
109.
110. # If this program was run (instead of imported), run the game:
111. if __name__ == '__main__':
112.     try:
113.         main()
114.     except KeyboardInterrupt:
115.         sys.exit() # When Ctrl-C is pressed, end the program.

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Add randomly created lakes and rivers, which act as fire breaks that flames cannot cross.
- Add a percentage chance that a tree will catch fire from its neighbor.
- Add different types of trees with different chances of catching fire.
- Add different states of burning trees so that it takes multiple simulation steps for a tree to burn down.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `bext.fg('green')` on line 96 to `bext.fg('random')`?
2. What happens if you change `EMPTY = ' '` on line 23 to `EMPTY = '.'`?
3. What happens if you change `forest.get((x + ix, y + iy)) == TREE` on line 66 to `forest.get((x + ix, y + iy)) == EMPTY`?
4. What happens if you change `nextForest[(x, y)] = EMPTY` on line 69 to `nextForest[(x, y)] = FIRE`?
5. What happens if you change `forest[(x, y)] = EMPTY` on line 86 to `forest[(x, y)] = TREE`?

#30

FOUR IN A ROW

In this classic tile-dropping board game for two players, you must try to get four of your tiles in a row horizontally, vertically, or diagonally, while preventing your opponent from doing the same. This program is similar to Connect Four.

The Program in Action

When you run *fourinarow.py*, the output will look like this:

Four in a Row, by Al Sweigart al@inventwithpython.com

--snip--

```
1234567
+-----+
|. . . . .|
|. . . . .|
|. . . . .|
|. . . . .|
|. . . . .|
+-----+
```

Player X, enter a column or QUIT:

> 3

```
1234567
+-----+
|. . . . .|
|. . . . .|
|. . . . .|
|. . . . .|
|. . X . .|
+-----+
```

Player O, enter a column or QUIT:

> 5

--snip--

Player O, enter a column or QUIT:

> 4

```
1234567
+-----+
|. . . . .|
|. . . . .|
|XXX.XO.|
|O000XO.|
|O00XOX.|
|OXXXOXX|
+-----+
```

Player O has won!

How It Works

The board game projects in this book follow a similar program structure. There's often a dictionary or list for representing the state of the board, a `getNewBoard()` function that returns a data structure for a board, a `displayBoard()` function for rendering a board data structure on the screen, and so on. You can check out the other projects in this book with the *board game* tag and compare them with each other, especially when you want to create your own original board game programs.

171.     return False
172.
173.
174. # If the program is run (instead of imported), run the game:
175. if __name__ == '__main__':
176.     main()

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Create a three-in-a-row or five-in-a-row variant.
- Make a three-player variant of this game.
- Add a “wildcard” tile that randomly drops after the players’ turns and can be used by either player.
- Add “block” tiles that cannot be used by either player.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `PLAYER_0 = '0'` on line 11 to `PLAYER_0 = 'X'`?
2. What happens if you change `return (columnIndex, rowIndex)` on line 116 to `return (columnIndex, 0)`?
3. What happens if you change `response == 'QUIT'` on line 98 to `response != 'QUIT'`?
4. What error message do you get if you change `tileChars = []` on line 72 to `tileChars = {}`?

#31

GUESS THE NUMBER

Guess the Number is a classic game for beginners to practice basic programming techniques. In this game, the computer thinks of a random number between 1 and 100. The player has 10 chances to guess the number. After each guess, the computer tells the player if it was too high or too low.

The Program in Action

When you run *guess.py*, the output will look like this:

```
Guess the Number, by Al Sweigart al@inventwithpython.com
```

```
I am thinking of a number between 1 and 100.  
You have 10 guesses left. Take a guess.  
> 50  
Your guess is too high.  
You have 9 guesses left. Take a guess.  
> 25  
Your guess is too low.  
--snip--  
You have 5 guesses left. Take a guess.  
> 42  
Yay! You guessed my number!
```

How It Works

Guess the Number uses several basic programming concepts: loops, if-else statements, functions, method calls, and random numbers. Python’s `random` module generates pseudorandom numbers—numbers that look random but are technically predictable. Pseudorandom numbers are easier for computers to generate than truly random numbers, and they’re considered “random enough” for applications such as video games and some scientific simulations.

Python’s `random` module produces pseudorandom numbers from a seed value, and each stream of pseudorandom numbers generated from the same seed will be the same. For example, enter the following into the interactive shell:

```
>>> import random  
>>> random.seed(42)  
>>> random.randint(1, 10); random.randint(1, 10); random.randint(1, 10)  
2  
1  
5
```

If you restart the interactive shell and run this code again, it produces the same pseudorandom numbers: 2, 1, 5. The video game *Minecraft* generates its pseudorandom virtual worlds from a starting seed value, which is why different players can re-create the same world by using the same seed.

-
1. """Guess the Number, by Al Sweigart al@inventwithpython.com
 2. Try to guess the secret number based on hints.
 3. View this code at <https://nostarch.com/big-book-small-python-projects>
 4. Tags: tiny, beginner, game"""
 - 5.
 6. `import random`
 - 7.

```

8.
9. def askForGuess():
10.     while True:
11.         guess = input('> ') # Enter the guess.
12.
13.         if guess.isdecimal():
14.             return int(guess) # Convert string guess to an integer.
15.         print('Please enter a number between 1 and 100.')
16.
17.
18. print('Guess the Number, by Al Sweigart al@inventwithpython.com')
19. print()
20. secretNumber = random.randint(1, 100) # Select a random number.
21. print('I am thinking of a number between 1 and 100.')
22.
23. for i in range(10): # Give the player 10 guesses.
24.     print('You have {} guesses left. Take a guess.'.format(10 - i))
25.
26.     guess = askForGuess()
27.     if guess == secretNumber:
28.         break # Break out of the for loop if the guess is correct.
29.
30.     # Offer a hint:
31.     if guess < secretNumber:
32.         print('Your guess is too low.')
33.     if guess > secretNumber:
34.         print('Your guess is too high.')
35.
36. # Reveal the results:
37. if guess == secretNumber:
38.     print('Yay! You guessed my number!')
39. else:
40.     print('Game over. The number I was thinking of was', secretNumber)

```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Create a “Guess the Letter” variant that gives hints based on the alphabetical order of the player’s guess.
- Make the hints after each guess say “warmer” or “colder” based on the player’s previous guess.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `input('> ')` on line 11 to `input(secretNumber)`?
2. What error message do you get if you change `return int(guess)` on line 14 to `return guess`?

3. What happens if you change `random.randint(1, 100)` on line 20 to `random.randint(1, 1)`?
4. What happens if you change `format(10 - i)` on line 24 to `format(i)`?
5. What error message do you get if you change `guess == secretNumber` on line 37 to `guess = secretNumber`?

#32

GULLIBLE

In this short and simple program, you can learn the secret and subtle art of keeping a gullible person busy for hours. I won't spoil the punch line here. Copy the code and run it for yourself. This project is great for beginners, whether you're smart or . . . not so smart.

The Program in Action

When you run *gullible.py*, the output will look like this:

```
Gullible, by Al Sweigart al@inventwithpython.com
Do you want to know how to keep a gullible person busy for hours? Y/N
> y
Do you want to know how to keep a gullible person busy for hours? Y/N
> y
Do you want to know how to keep a gullible person busy for hours? Y/N
> yes
Do you want to know how to keep a gullible person busy for hours? Y/N
> YES
Do you want to know how to keep a gullible person busy for hours? Y/N
> TELL ME HOW TO KEEP A GULLIBLE PERSON BUSY FOR HOURS
"TELL ME HOW TO KEEP A GULLIBLE PERSON BUSY FOR HOURS" is not a valid yes/no
response.
Do you want to know how to keep a gullible person busy for hours? Y/N
> y
Do you want to know how to keep a gullible person busy for hours? Y/N
> y
Do you want to know how to keep a gullible person busy for hours? Y/N
> n
Thank you. Have a nice day!
```

How It Works

To be more user friendly, your programs should attempt to interpret a range of possible inputs from the user. For example, this program asks the user a yes/no question, but it would be simpler for the player to simply enter “y” or “n” instead of enter the full word. The program can also understand the player’s intent if their CAPS LOCK key is activated, because it calls the `lower()` string method on the string the player entered. This way, 'y', 'yes', 'Y', 'Yes', and 'YES', are all interpreted the same by the program. The same goes for a negative response from the player.

```
1. """Gullible, by Al Sweigart al@inventwithpython.com
2. How to keep a gullible person busy for hours. (This is a joke program.)
3. View this code at https://nostarch.com/big-book-small-python-projects
4. Tags: tiny, beginner, humor"""
5.
6. print('Gullible, by Al Sweigart al@inventwithpython.com')
7.
8. while True: # Main program loop.
9.     print('Do you want to know how to keep a gullible person busy for
10.         hours? Y/N')
11.     response = input('> ') # Get the user's response.
12.     if response.lower() == 'no' or response.lower() == 'n':
13.         break # If "no", break out of this loop.
14.     if response.lower() == 'yes' or response.lower() == 'y':
15.         continue # If "yes", continue to the start of this loop.
```

15. `print("{}" is not a valid yes/no response.'.format(response))`
 - 16.
 17. `print('Thank you. Have a nice day!')`
-

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `response.lower() == 'no'` on line 11 to `response.lower() != 'no'`?
2. What happens if you change `while True:` on line 8 to `while False:?`

#33

HACKING MINIGAME

In this game, the player must hack a computer by guessing a seven-letter word used as the secret password. The computer's memory banks display the possible words, and the player is given hints as to how close each guess was. For example, if the secret password is **MONITOR** but the player guessed **CONTAIN**, they are given the hint that two out of seven letters were correct, because both **MONITOR** and **CONTAIN** have the letter *O* and *N* as their second and third letter. This game is similar to Project 1, "Bagels," and the hacking minigame in the *Fallout* series of video games.

The Program in Action

When you run *hacking.py*, the output will look like this:

```
Hacking Minigame, by Al Sweigart al@inventwithpython.com
Find the password in the computer's memory:
0x1150 $],>@|~RESOLVE^      0x1250 {>+)<!?CHICKEN,%
0x1160 }@% _-:;/$^(|<|!(    0x1260 .][})?#@#ADDRESS
0x1170 _;)][#?<&~$~+&}}      0x1270 ,#=>{-;/DESPITE
0x1180 %[!]{REFUGEE@?~,      0x1280 }/.)!-DISPLAY%/
0x1190 _[^%[@]^<_{_@$~      0x1290 =>>,:%?_?@+{#.#
0x11a0 )?~/)+PENALTY?-=      0x12a0 >[,?*#IMPROVE@$/
--snip--
Enter password: (4 tries remaining)
> resolve
Access Denied (2/7 correct)
Enter password: (3 tries remaining)
> improve
A C C E S S   G R A N T E D
```

How It Works

This game has a hacking theme, but it doesn't involve any actual computer hacking. If we'd just listed the possible words on the screen, the gameplay would have been identical. However, the cosmetic additions that mimic a computer's memory banks convey an exciting feeling of computer hacking. The attention to detail and user experience turn a plain, boring game into an exciting one.

169.         guess = input('> ').upper()
170.         if guess in words:
171.             return guess
172.         print('That is not one of the possible passwords listed above.')
173.         print('Try entering "{}" or "{}".'.format(words[0], words[1]))
174.
175.
176. # If this program was run (instead of imported), run the game:
177. if __name__ == '__main__':
178.     try:
179.         main()
180.     except KeyboardInterrupt:
181.         sys.exit() # When Ctrl-C is pressed, end the program.

```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Find a word list on the internet and create your own *sevenletterwords.txt* file, maybe one with six- or eight-letter words.
- Create a different visualization of the “computer memory.”

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `for j in range(16):` on line 133 to `for j in range(0):`?
2. What happens if you change `GARBAGE_CHARS = '~!@#$$%^&*()_+={}[|];:,.<>?/'` on line 14 to `GARBAGE_CHARS = '.''`?
3. What happens if you change `gameWords = getWords()` on line 34 to `gameWords = ['MALKOVICH'] * 20`?
4. What error message do you get if you change `return words` on line 94 to `return`?
5. What happens if you change `randomWord = random.choice(WORDS)` on line 103 to `secretPassword = 'PASSWORD'`?

#34

HANGMAN AND GUILLOTINE

This classic word game has the player guess the letters to a secret word. For each incorrect letter, another part of the hangman is drawn. Try to guess the complete word before the hangman completes. The secret words in this version are all animals like RABBIT and PIGEON, but you can replace these with your own set of words.

The `HANGMAN_PICS` variable contains ASCII-art strings of each step of the hangman's noose:

```
+++  +++  +++  +++  +++  +++  +++  
|    |    |    |    |    |    |  
|    0    0    0    0    0    0  
|    |    |    /|   /|  /|  /|\  
|    |    |    |    |    |    |  
|    |    |    |    |    |    |  
=====
```

For a French twist on the game, you can replace the strings in the `HANGMAN_PICS` variable with the following strings depicting a guillotine:

```
|        |    |    |===|    |===|    |===|    |===|    |===|
|        |    |    |    |    |    |    |    |    |    |
|        |    |    |    |    |    |    |    |    |    |
|        |    |    |    |    |    |    |    |    |    |
|        |    |    |    |    |    |    |    |    |    |
|        |    |    |    |    |    |    |    |    |    |
|===     |===|    |===|    |===|    |===|    |===|    |===|
```

The Program in Action

When you run `hangman.py`, the output will look like this:

```

```

```
Yes! The secret word is: OTTER
```

```
You have won!
```

How It Works

Hangman and Guillotine share the same game mechanics but have different presentations. This makes it easy to swap out the ASCII-art noose graphics with the ASCII-art guillotine graphics without having to change the main logic that the program follows. This separation of the presentation and logic parts of the program makes it easier to update with new features or different designs. In professional software development, this strategy is an example of a *software design pattern* or *software architecture*, which concerns itself with how to structure your programs for easy understanding and modification. This is mainly useful in large software applications, but you can also apply these principles to smaller projects.

161.
162.
163. # If this program was run (instead of imported), run the game:
164. if __name__ == '__main__':
165.     try:
166.         main()
167.     except KeyboardInterrupt:
168.         sys.exit() # When Ctrl-C is pressed, end the program.

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Add a “category select” feature and let the player choose what category of words they want to play.
- Add a selection feature so the player can choose between the hangman and guillotine versions of the game.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you delete or comment out `missedLetters.append(guess)` on line 108?
2. What happens if you change `drawHangman(missedLetters, correctLetters, secretWord)` on line 85 to `drawHangman(correctLetters, missedLetters, secretWord)`?
3. What happens if you change `['_']` on line 136 to `['*']`?
4. What happens if you change `print(' '.join(blanks))` on line 144 to `print(secretWord)`?

#35

HEX GRID

This short program produces a tessellated image of a hexagonal grid, similar to chicken wire. It shows that you don't need a lot of code to make something interesting. A slightly more complicated variation of this program is Project 65, "Shining Carpet."

Note that this program uses raw strings, which prefix the opening quote with a lowercase `r` so that the backslashes in the string aren't interpreted as escape characters.

The Program in Action

Figure 35-1 shows what the output will look like when you run `hexgrid.py`.

Figure 35-1: Output showing a tessellated image of a hexagonal grid

How It Works

The power behind programming is that it can make a computer carry out repetitive instructions quickly and without mistakes. This is how a dozen lines of code can create hundreds, thousands, or millions of hexagons on the screen.

In the Command Prompt or Terminal window, you can redirect a program's output from the screen to a text file. On Windows, run `py hexgrid.py > hextiles.txt` to create a text file that contains the hexagons. On Linux and macOS, run `python3 hexgrid.py > hextiles.txt`. Without the size of the screen as a limit, you can increase the `X_REPEAT` and `Y_REPEAT` constants and save the contents to a file. From there, it's easy to print the file on paper, send it in an email, or post it to social media. This applies to any computer-generated artwork you create.

- 5.
6. `# Set up the constants:`
7. `# (!) Try changing these values to other numbers:`
8. `X_REPEAT = 19 # How many times to tessellate horizontally.`
9. `Y_REPEAT = 12 # How many times to tessellate vertically.`
- 10.

```

11. for y in range(Y_REPEAT):
12.     # Display the top half of the hexagon:
13.     for x in range(X_REPEAT):
14.         print(r'/_ \'', end='')
15.     print()
16.
17.     # Display the bottom half of the hexagon:
18.     for x in range(X_REPEAT):
19.         print(r'\_/ ', end='')
20.     print()

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Create tiled hexagons of a larger size.
- Create tiled rectangular bricks instead of hexagons.

For practice, try re-creating this program with larger hexagon grids, such as the following patterns:

Exploring the Program

This is a base program, so there aren't many options to customize it. Instead, consider how you could similarly program patterns of other shapes.

#36

HOURGLASS

This visualization program has a rough physics engine that simulates sand falling through the small aperture of an hourglass.

The sand piles up in the bottom half of the hourglass; then the hourglass is turned over so the process repeats.

The Program in Action

Figure 36-1 shows what the output will look like when you run *hourglass.py*.

Figure 36-1: The output of the *hourglass* program with sand falling

How It Works

The *hourglass* program implements a rudimentary physics engine. A *physics engine* is software that simulates physical objects falling under gravity, colliding with each other, and moving according to the laws of physics. You'll find physics engines used in video games, computer animation, and scientific simulations. On lines 91 to 102, each "grain" of sand checks if the space beneath it is empty and moves down if it is. Otherwise, it checks if it can move down and to the left (lines 104 to 112) or down and to the right (lines 114 to 122). Of course, there is much more to *kinematics*, the branch of classical physics that deals with the motion of macroscopic objects, than this. However, you don't need a degree in physics to make a primitive simulation of sand in an hourglass that is enjoyable to look at.

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Create wall shapes other than an hourglass.
- Create points on the screen that continuously pour out new grains of sand.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `range(18, 37)` on line 31 to `range(18, 30)`?
2. What happens if you change `range(8)` on line 39 to `range(0)`?
3. What happens if you change `sandMovedOnThisStep = False` on line 82 to `sandMovedOnThisStep = True`?
4. What happens if you change `fallingDirection = None` on line 125 to `fallingDirection = 1`?
5. What happens if you change `random.random() * 100 <= WIDE_FALL_CHANCE` on line 136 to `random.random() * 0 <= WIDE_FALL_CHANCE`?

#37

HUNGRY ROBOTS

You are trapped in a maze with hungry robots! You don't know why robots need to eat, but you don't want to find out. The robots are badly programmed and will move directly toward you, even if blocked by walls. You must trick the robots into crashing into each other (or dead robots) without being caught.

You have a personal teleporter device that can send you to a random new place, but it only has enough battery for two trips. Also, you and the robots can slip through corners!

```

239.
240. # If this program was run (instead of imported), run the game:
241. if __name__ == '__main__':
242.     main()

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Create two different kinds of robots: those that can only move diagonally and those that can only move in cardinal directions.
- Give the player a limited number of traps they can leave behind to stop any robot that steps on one.
- Give the player a limited number of “instant walls” that they can put up for their own defense.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `WALL = chr(9617)` on line 22 to `WALL = 'R'`?
2. What happens if you change `return nextRobotPositions` on line 237 to `return robotPositions`?
3. What happens if you delete or comment out `displayBoard(board, robots, playerPosition)` on line 44?
4. What happens if you delete or comment out `robots = moveRobots(board, robots, playerPosition)` on line 53?

#38

J'ACCUSE!

You are the world-famous detective Mathilde Camus. Zophie the cat has gone missing, and you must sift through the clues. Suspects either always tell lies or always tell the truth.

Will you find Zophie the cat in time and accuse the guilty party?

In this game, you take a taxi to different locations around the city. At each location is a suspect and an item. You can ask suspects about other suspects and items, compare their answers with your own exploration notes, and determine if they are lying or telling the truth. Some will know who has catnapped Zophie (or where she is, or what item is found at the location of the kidnapper), but you must determine if you can believe them. You have five minutes to find the criminal but will lose if you make three wrong accusations. This game is inspired by Homestar Runner's "Where's an Egg?" game.

The Program in Action

When you run *jaccuse.py*, the output will look like this:

```
J'ACCUSE! (a mystery game)
--snip--
Time left: 5 min, 0 sec
  You are in your TAXI. Where do you want to go?
(A)LBINO ALLIGATOR PIT
(B)OWLING ALLEY
(C)ITY HALL
(D)UCK POND
(H)IPSTER CAFE
(O)LD BARN
(U)NIVERSITY LIBRARY
(V)IDEO GAME MUSEUM
(Z)OO
> a

Time left: 4 min, 48 sec
  You are at the ALBINO ALLIGATOR PIT.
  ESPRESSA TOFFEEPOT with the ONE COWBOY BOOT is here.

(J) "J'ACCUSE!" (3 accusations left)
(Z) Ask if they know where ZOPHIE THE CAT is.
(T) Go back to the TAXI.
(1) Ask about ESPRESSA TOFFEEPOT
(2) Ask about ONE COWBOY BOOT
> z
  They give you this clue: "DUKE HAUTDOG"
  Press Enter to continue...
--snip--
```

How It Works

To fully understand this program, you should pay close attention to the clues dictionary, which is set up on lines 51 to 109. You can uncomment lines 151 to 154 to display it on the screen. This dictionary has strings from the SUSPECTS list for the keys and “clue dictionaries” for the values. Each of these clue dictionaries contains strings from SUSPECTS and ITEMS. The original suspect will answer with these strings when asked about another suspect or item. For example, if `clues['DUKE HAUTDOG']['CANDLESTICK']` is set to `'DUCK POND'`, then when the player asks Duke Hautdog about the Candlestick, they'll say it is at the Duck Pond. The suspects, items, locations, and culprit get shuffled each time the game is played.

The code for this program revolves around this data structure, so understanding it is necessary to unlocking your understanding of the rest of the program.

```

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `TIME_TO_SOLVE = 300` on line 16 to `TIME_TO_SOLVE = 0`?
2. What happens if you change `time.time() > endTime` or `accusationsLeft == 0` on line 176 to `time.time() > endTime` and `accusationsLeft == 0`?
3. What happens if you change `place[1:]` on line 198 to `place`?
4. What happens if you change `startTime + TIME_TO_SOLVE` on line 173 to `startTime * TIME_TO_SOLVE`?

#39

LANGTON'S ANT

Langton's Ant is a cellular automata simulation on a two-dimensional grid, similar to Project 13, "Conway's Game of Life." In the simulation, an "ant" begins on a square that is one of two colors. If the space is the first color, the ant switches it to the second color, turns 90 degrees to the right, and moves forward one space. If the space is the second color, the ant switches it to the first color, turns 90 degrees to the left, and moves forward one space.

Despite the very simple set of rules, the simulation displays complex emergent behavior. Simulations can feature multiple ants in the same space, causing interesting interactions when they cross paths with each other. Langton's Ant was invented by computer scientist Chris Langton in 1986. More information about Langton's Ant can be found at https://en.wikipedia.org/wiki/Langton%27s_ant.

The Program in Action

Figure 39-1 shows what the output will look like when you run *langtonsant.py*.

Figure 39-1: The hypnotic output of the Langton's Ant cellular automata

How It Works

This program uses two senses of “direction.” On the one hand, the dictionaries that represent each ant store *cardinal directions*: north, south, east, and west. However, turning left or right (or counterclockwise and clockwise, since we are viewing the ants from above) is a *rotational direction*. Ants are supposed to turn left or right in response to the tile they're standing on, so lines 78 to 100 set a new cardinal direction based on the ant's current cardinal direction and the direction they are turning.

150.
151. # Display the quit message at the bottom of the screen:
152. bext.goto(0, HEIGHT)
153. bext.bg(WHITE_TILE)
154. print('Press Ctrl-C to quit.', end='')
155.
156. sys.stdout.flush() # (Required for bext-using programs.)
157. time.sleep(PAUSE_AMOUNT)
158.
159.
160. # If this program was run (instead of imported), run the game:
161. if __name__ == '__main__':
162.     try:
163.         main()
164.     except KeyboardInterrupt:
165.         print("Langton's Ant, by Al Sweigart al@inventwithpython.com")
166.         sys.exit() # When Ctrl-C is pressed, end the program.

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Let the player load and save the state of the board's tiles from and to a text file.
- Create additional tile states with new rules of movement and see what behavior emerges.
- Implement some of the ideas suggested in the Wikipedia article for Langton's Ant.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `print(' ', end='')` on line 149 to `print('.', end='')`?
2. What happens if you change `ant['y'] += 1` on line 106 to `ant['y'] -= 1`?
3. What happens if you change `nextBoard[(ant['x'], ant['y'])] = False` on line 79 to `nextBoard[(ant['x'], ant['y'])] = True`?
4. What happens if you change `WIDTH -= 1` on line 21 to `WIDTH -= 40`?
5. What happens if you change `board = nextBoard` on line 119 to `board = board`?

#40

LEETSPEAK

There's no better way to demonstrate your mad hacker skills than by replacing letters in your text with numbers: m4d h4x0r 5k1llz!!! This word program automatically converts plain English into leetspeak, the coolest way to talk online. Or at least it was in 1993.

It takes a while to get used to, but with some practice, you'll eventually be able to read leetspeak fluently. For example, 1t +@]<3s 4 w|-|1le +o g37 |_|s3|) 70, b|_|+ you (an 3\|3nt|_|/-\|ly r3a|) l33t\$peak ph1|_|3n+ly. Leetspeak may be hard to read at first, but the program itself is simple and good for beginners. More information about leetspeak can be found at <https://en.wikipedia.org/wiki/Leet>.

The Program in Action

When you run *leetspeak.py*, the output will look like this:

```
L3375P34]< (leetspeak)
By Al Sweigart al@inventwithpython.com

Enter your leet message:
> I am a leet hacker. Fear my mad skills. The 90s were over two decades ago.

! @m a l33t h@(<er. ph3@r my m4|) $k|ll$. +h3 90s w3r3 Over tw0 d3(ad3$ 4g0.
(Copied leetspeak to clipboard.)
```

How It Works

The dictionary in the `charMapping` variable on line 36 maps plain English characters to leetspeak characters. However, since there can be multiple possible leetspeak characters (such as '7' or '+' for the letter 't'), each value in the `charMapping` dictionary is a list of strings. When creating the new leetspeak string, the program has a 30 percent chance of simply using the character in the original English message and a 70 percent chance of using one of the leetspeak characters. This means the same English message has multiple possible leetspeak translations.

5.
6. import random
7.
8. try:
9.     import pyperclip # pyperclip copies text to the clipboard.
10. except ImportError:
11.     pass # If pyperclip is not installed, do nothing. It's no big deal.
12.
13.
14. def main():
15.     print('L3375P34]< (leetspeak)
16. By Al Sweigart al@inventwithpython.com
17.
18. Enter your leet message:')
19.     english = input('> ')
20.     print()
21.     leetspeak = englishToLeetspeak(english)
22.     print(leetspeak)
23.
24.     try:
25.         # Trying to use pyperclip will raise a NameError exception if
26.         # it wasn't imported:
27.         pyperclip.copy(leetspeak)
28.         print('(Copied leetspeak to clipboard.)')
```

```

29.     except NameError:
30.         pass # Do nothing if pyperclip wasn't installed.
31.
32.
33. def englishToLeetspeak(message):
34.     """Convert the English string in message and return leetspeak."""
35.     # Make sure all the keys in `charMapping` are lowercase.
36.     charMapping = {
37.         'a': ['4', '@', '/-\\'], 'c': ['('], 'd': ['|']}, 'e': ['3'],
38.         'f': ['ph'], 'h': ['-|', '|-|'], 'i': ['1', '!', '|'], 'k': ['<'],
39.         'o': ['0'], 's': ['$', '5'], 't': ['7', '+'], 'u': ['|_'],
40.         'v': ['\\\/']}
41.     leetspeak = ''
42.     for char in message: # Check each character:
43.         # There is a 70% chance we change the character to leetspeak.
44.         if char.lower() in charMapping and random.random() <= 0.70:
45.             possibleLeetReplacements = charMapping[char.lower()]
46.             leetReplacement = random.choice(possibleLeetReplacements)
47.             leetspeak = leetspeak + leetReplacement
48.         else:
49.             # Don't translate this character:
50.             leetspeak = leetspeak + char
51.     return leetspeak
52.
53.
54. # If this program was run (instead of imported), run the game:
55. if __name__ == '__main__':
56.     main()

```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Modify the `charMapping` dictionary so that it supports new leetspeak characters.
- Add a feature that can convert leetspeak back into plain English.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `return leetspeak` on line 51 to `return message`?
2. What happens if you change `char.lower()` on line 44 to `char`?
3. What happens if you change `char.lower()` on line 44 to `char.upper()`?
4. What happens if you change `leetspeak = leetspeak + leetReplacement` on line 47 to `leetspeak = leetReplacement`?

#41

LUCKY STARS

In this push-your-luck game, you roll dice to collect stars. The more you roll, the more stars you can get, but if you get three skulls you lose everything! This quick multiplayer game can support as many players as you want, making it ideal for parties.

On your turn, you pull three random dice from the dice cup and roll them. You can roll Stars, Skulls, and Question Marks. If you end your turn, you get one point per Star. If you choose to roll again, you keep the Question Marks and pull new dice to replace the Stars and Skulls. If you collect three Skulls, you lose all your Stars and end your turn.

When a player gets 13 points, everyone else gets one more turn before the game ends. Whoever has the most points wins.

There are six gold dice, four silver dice, and three bronze dice in the cup. Gold dice have more Stars, bronze dice have more Skulls, and silver is even.

The Program in Action

When you run `luckystars.py`, the output will look like this:

```
Lucky Stars, by Al Sweigart al@inventwithpython.com
```

```
--snip--
```

```
SCORES: Alice=0, Bob=0
```

```
It is Alice's turn.

```

How It Works

The text-based graphics in this program are stored as strings in a list in the `STAR_FACE`, `SKULL_FACE`, and `QUESTION_FACE` variables. This format makes them easy to write in a code editor, while the code in lines 154 to 157 display them on the screen. Note that because three dice are shown together, this code must print each horizontal row of text on a die face at a time. Simply running code like `print(STAR_FACE)` would result in each of the three dice appearing on top of each other, instead of side by side.

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you delete or comment out `random.shuffle(cup)` on line 114?
2. What happens if you change `skulls >= 3` on line 167 to `skulls > 3`?
3. What error message do you get if you change `(turn + 1) % numPlayers` on line 206 to `(turn + 1)`?
4. What happens if you change `endGameWith = None` on line 84 to `endGameWith = playerNames[0]`?
5. What happens if you delete or comment out `break` on line 170?
6. What happens if you change `playerScores[response] = 0` on line 76 to `playerScores[response] = 10`?

#42

MAGIC FORTUNE BALL

The Magic Fortune Ball can predict the future and answer your yes/no questions with 100 percent accuracy using the power of Python's random number module. This program is similar to a Magic 8 Ball toy, except you don't have to shake it. It also features a function for slowly printing text strings with spaces in between each character, giving the messages a spooky, mysterious effect.

Most of the code is dedicated to setting the eerie atmosphere. The program itself simply selects a message to display in response to a random number.

The Program in Action

When you run *magicfortuneball.py*, the output will look like this:

```
M A G I C   F O R T U N E   B A L L ,   B Y   A L   S W E I G A R T

A S K   M E   Y O U R   Y E S / N O   Q U E S T I O N .

How It Works

The only thing the Magic Fortune Ball actually does is display a randomly chosen string. It completely ignores the user's question. Sure, line 28 calls `input('> ')`, but it doesn't store the return value in any variable because the program doesn't actually use this text. Letting users enter their questions gives them the sense that the program has an aura of clairvoyance.

The `slowSpacePrint()` function displays the uppercase text with any letter *I* in lowercase, making the message look unique. The function also inserts spaces between each character of the string and then displays them slowly, with pauses. A program doesn't need to be sophisticated enough to predict the future to be fun!

```

61.     'NO, BUT YOU MAY WISH IT WAS SO',
62. ]
63. slowSpacePrint(random.choice(answers), 0.05)

```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Check that the player's question ends in a question mark.
- Add other answers the program can give.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `random.randint(4, 12)` on line 45 to `random.randint(4, 9999)`?
2. What error do you get if you change `time.sleep(1)` on line 49 to `time.sleep(-1)`?

#43

MANCALA

The board game Mancala is at least 2,000 years old, making it almost as old as Project 63, “Royal Game of Ur.” It is a “seed-sowing” game in which two players select pockets of seeds to spread across the other pockets on the board while trying to collect as many in their store as possible. There are several variants of this game across different cultures. The name comes from the Arab word *naqala*, meaning “to move.”

To play, grab the seeds from a pit on your side of the board and place one in each subsequent pit, going counterclockwise and skipping your opponent’s store. If your last seed lands in an empty pit of yours, move the opposite pit’s seeds into that pit. If the last placed seed is in your store, you get a free turn.

The game ends when all of one player's pits are empty. The other player claims the remaining seeds for their store, and the winner is the one with the most seeds. More information about Mancala and its variants can be found at <https://en.wikipedia.org/wiki/Mancala>.

The Program in Action

When you run *mancala.py*, the output will look like this:

```
Mancala, by Al Sweigart al@inventwithpython.com
--snip--

+-----+-----+<<<<<-Player 2-----+-----+-----+
2      |G   |H   |I   |J   |K   |L   |   | 1

T  0  +-----+-----+-----+-----+-----+ 1 T
O      |A   |B   |C   |D   |E   |F   |   | O
R      | 4  | 4  | 4  | 4  | 4  | 0  |   | R
E      |   |   |   |   |   |   |   | E
+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+
+-----+-----+<<<<<-Player 1->>>>>-----+-----+-----+
Player 2, choose move: G-L (or QUIT)
--snip--
```

How It Works

Mancala uses ASCII art to display the board. Notice that each pocket needs to have not only the number of seeds in it but a label as well. To avoid confusion, the labels use the letters *A* through *L* so they won't be mistaken for the number of seeds in each pocket. The dictionaries `NEXT_PIT` and `OPPOSITE_PIT` map the letter of one pocket to the letter of the pit next to or opposite it, respectively. This lets the expression `NEXT_PIT['A']` evaluate to `'B'` and the expression `OPPOSITE_PIT['A']` evaluate to `'G'`. Pay attention to how the code uses these dictionaries. Without them, our Mancala program would require long series of `if` and `elif` statements to carry out the same game steps.

184.     seeds for their store. The winner is whoever has the most seeds."""
185.
186.     player1Total = board['A'] + board['B'] + board['C']
187.     player1Total += board['D'] + board['E'] + board['F']
188.     player2Total = board['G'] + board['H'] + board['I']
189.     player2Total += board['J'] + board['K'] + board['L']
190.
191.     if player1Total == 0:
192.         # Player 2 gets all the remaining seeds on their side:
193.         board['2'] += player2Total
194.         for pit in PLAYER_2_PITS:
195.             board[pit] = 0 # Set all pits to 0.
196.     elif player2Total == 0:
197.         # Player 1 gets all the remaining seeds on their side:
198.         board['1'] += player1Total
199.         for pit in PLAYER_1_PITS:
200.             board[pit] = 0 # Set all pits to 0.
201.     else:
202.         return 'no winner' # No one has won yet.
203.
204.     # Game is over, find player with largest score.
205.     if board['1'] > board['2']:
206.         return '1'
207.     elif board['2'] > board['1']:
208.         return '2'
209.     else:
210.         return 'tie'
211.
212.
213. # If the program is run (instead of imported), run the game:
214. if __name__ == '__main__':
215.     main()

```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Change the board to have more pits.
- Randomly select a bonus pit that, when the last seed lands in it, lets the player take another turn.
- Create a square-shaped board for four players instead of two.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `return '2'` on line 175 to `return '1'`?
2. What happens if you change `return '2'` on line 208 to `return '1'`?
3. What happens if you change `response == 'QUIT'` on line 125 to `response == 'quit'`?
4. What happens if you change `board[pit] = 0` on line 147 to `board[pit] = 1`?
5. What happens if you change `print('\n' * 60)` on line 53 to `print('\n' * 0)`?
6. What happens if you change `playerTurn = '1'` on line 48 to `playerTurn = '2'`?
7. What happens if you change `board.get(response) == 0` on line 135 to `board.get(response) == -1`?

#44

MAZE RUNNER 2D

This two-dimensional maze runner shows the player a top-down, bird's-eye view of a maze file you create in a text editor, such as the IDE you use to write your *.py* files. Using the WASD keys, the player can move up, left, down, and right, respectively, to navigate the @ symbol toward the exit marked by the X character.

To make a maze file, open a text editor and create the following pattern. Don't type the numbers along the top and left side; they are only there for reference:

```
123456789
1#####
2#S# # # #
3#####
4# # # # #
5#####
```

How It Works

The program loads the data for the maze's walls from a text file and into a dictionary stored in the `maze` variable. This dictionary has `(x, y)` tuples for keys and the string in the `WALL`, `EMPTY`, `START`, or `EXIT` constants for values. Project 45, "Maze Runner 3D," uses a similar dictionary representation of the maze. The difference between the projects is in the code that renders that maze on the screen. Since Maze Runner 2D is simpler, I recommend becoming familiar with this program first before moving on to Maze Runner 3D.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What error message do you get if you change `character == START` on line 74 to `character == EXIT`?
2. What happens if you change `playery + 1` on line 105 to `playery - 1`?
3. What happens if you change `(exitx, exity)` on line 156 to `(None, None)`?
4. What error message do you get if you change `while True:` on line 89 to `while False:`?
5. What happens if you change `break` on line 104 to `continue`?
6. What error message do you get if you change `break` on line 121 to `continue`?

#45

MAZE RUNNER 3D

This three-dimensional maze runner provides the player with a first-person view from inside a maze. Try to find your way out!

You can generate maze files by following the instructions in Project 44, “Maze Runner 2D,” or by downloading maze files from <https://invpy.com/mazes/>.

The periods in the ASCII art in the source code get removed before the strings are displayed; they only exist to make entering the code easier, so you don't insert or leave out blank spaces.

Here is the source code for the 3D maze:

```

1. """Maze 3D, by Al Sweigart al@inventwithpython.com
2. Move around a maze and try to escape... in 3D!
3. View this code at https://nostarch.com/big-book-small-python-projects
4. Tags: extra-large, artistic, game, maze"""
5.
6. import copy, sys, os

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What bug do you cause if you change `move == 'QUIT'` on line 279 to `move == 'quit'`?
2. How can you remove the teleportation cheat?

#46

MILLION DICE ROLL STATISTICS SIMULATOR

When you roll two six-sided dice, there's a 17 percent chance you'll roll a 7. That's much better than the odds of rolling a 2: just 3 percent. That's because there's only one combination of dice rolls that gives you 2 (the one that occurs when both dice roll a 1), but many combinations add up to seven: 1 and 6, 2 and 5, 3 and 4, and so on.

But what about when you roll three dice? Or four? Or 1,000? You could mathematically calculate the theoretical probabilities, or you can have the computer roll a number of dice one million times to empirically figure them out. This program takes that latter approach. In this program, you tell the computer to roll N dice one million times and remember the results. It then displays the percentage chance of each sum.

This program does a massive amount of computation, but the computation itself isn't hard to understand.

The Program in Action

When you run *milliondicestats.py*, the output will look like this:

```
Million Dice Roll Statistics Simulator
By Al Sweigart al@inventwithpython.com

Enter how many six-sided dice you want to roll:
> 2
Simulating 1,000,000 rolls of 2 dice...
36.2% done...
73.4% done...
TOTAL - ROLLS - PERCENTAGE
 2 - 27590 rolls - 2.8%
 3 - 55730 rolls - 5.6%
 4 - 83517 rolls - 8.4%
 5 - 111526 rolls - 11.2%
 6 - 139015 rolls - 13.9%
 7 - 166327 rolls - 16.6%
 8 - 139477 rolls - 13.9%
 9 - 110268 rolls - 11.0%
10 - 83272 rolls - 8.3%
11 - 55255 rolls - 5.5%
12 - 28023 rolls - 2.8%
```

How It Works

We simulate the roll of a single six-sided die by calling `random.randint(1, 6)` on line 30. This returns a random number between 1 and 6, which gets added to the running total for however many dice are rolled together. The `random.randint()` function has a uniform distribution, meaning each number is just as likely as any other to be returned.

The program stores the results of this roll with the results dictionary. The keys to this dictionary are each possible dice roll total, and the values are how many times this total has been encountered. To get the frequency percentage, we divide the number of times a total has been encountered by 1,000,000 (the number of dice rolls in this simulation) and multiply it by 100 (to get a percentage between 0.0 and 100.0 instead of 0.0 and 1.0). By doing some algebra, we can figure out that this is the same as dividing the number of encounters by 10,000, which we do on line 37.

```

2. By Al Sweigart al@inventwithpython.com
3. A simulation of one million dice rolls.
4. View this code at https://nostarch.com/big-book-small-python-projects
5. Tags: tiny, beginner, math, simulation"""
6.
7. import random, time
8.
9. print('Million Dice Roll Statistics Simulator
10. By Al Sweigart al@inventwithpython.com
11.
```

```

12. Enter how many six-sided dice you want to roll:''')
13. numberOfDice = int(input('> '))
14.
15. # Set up a dictionary to store the results of each dice roll:
16. results = {}
17. for i in range(numberOfDice, (numberOfDice * 6) + 1):
18.     results[i] = 0
19.
20. # Simulate dice rolls:
21. print('Simulating 1,000,000 rolls of {} dice...'.format(numberOfDice))
22. lastPrintTime = time.time()
23. for i in range(1000000):
24.     if time.time() > lastPrintTime + 1:
25.         print('{}% done...'.format(round(i / 10000, 1)))
26.         lastPrintTime = time.time()
27.
28.     total = 0
29.     for j in range(numberOfDice):
30.         total = total + random.randint(1, 6)
31.     results[total] = results[total] + 1
32.
33. # Display results:
34. print('TOTAL - ROLLS - PERCENTAGE')
35. for i in range(numberOfDice, (numberOfDice * 6) + 1):
36.     roll = results[i]
37.     percentage = round(results[i] / 10000, 1)
38.     print(' {} - {} rolls - {}'.format(i, roll, percentage))

```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Try rolling 8-, 10-, 12-, or 20-sided dice.
- Try simulating two-sided coin tosses.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `lastPrintTime + 1` on line 24 to `lastPrintTime + 2`?
2. What bug do you cause if you delete or comment out `results[total] = results[total] + 1` on line 31?
3. What error happens if the user types letters instead of a number for the number of six-sided dice to roll?

#47

MONDRIAN ART GENERATOR

Piet Mondrian was a 20th-century Dutch painter and one of the founders of neoplasticism, an abstract art movement. His most iconic paintings relied on blocks of primary colors (blue, yellow, red), black, and white. Using a minimalist approach, he separated these colors with horizontal and vertical elements.

This program generates random paintings that follow Mondrian's style. You can find out more about Piet Mondrian at https://en.wikipedia.org/wiki/Piet_Mondrian.

The Program in Action

The next module allows our Python program to display bright primary colors in the text output, even though this book only shows black-and-white images. Figure 47-1 shows what the output will look like when you run *mondrian.py*.

Figure 47-1: The Mondrian art program's computer-generated art. A different image is generated each time the program runs.

How It Works

The algorithm works by creating a data structure (the canvas dictionary) with randomly spaced vertical and horizontal lines, as in Figure 47-2.

Figure 47-2: The first step of the Mondrian art algorithm creates a grid.

Next, it removes some of the line segments to create larger rectangles, as shown in Figure 47-3.

Figure 47-3: The second step of the Mondrian art algorithm removes some lines at random.

Finally, the algorithm randomly fills some rectangles with yellow, red, blue, or black, as in Figure 47-4.

Figure 47-4: The third step of the Mondrian art algorithm randomly selects rectangles to fill with color.

You can find another version of this Mondrian art generator at https://github.com/asweigart/mondrian_art_generator/ along with several sample images.

158.                 colorToPaint = random.choice([RED, YELLOW, BLUE, BLACK])
159.                 pointsToPaint = set([(startx, starty)])
160.                 while len(pointsToPaint) > 0:

```

```

161.         x, y = pointsToPaint.pop()
162.         canvas[(x, y)] = colorToPaint
163.         if canvas[(x - 1, y)] == WHITE:
164.             pointsToPaint.add((x - 1, y))
165.         if canvas[(x + 1, y)] == WHITE:
166.             pointsToPaint.add((x + 1, y))
167.         if canvas[(x, y - 1)] == WHITE:
168.             pointsToPaint.add((x, y - 1))
169.         if canvas[(x, y + 1)] == WHITE:
170.             pointsToPaint.add((x, y + 1))
171.
172.     # Draw the canvas data structure:
173.     for y in range(height):
174.         for x in range(width):
175.             bext.bg(canvas[(x, y)])
176.             print(' ', end='')
177.
178.         print()
179.
180.     # Prompt user to create a new one:
181.     try:
182.         input('Press Enter for another work of art, or Ctrl-C to quit.')
183.     except KeyboardInterrupt:
184.         sys.exit()

```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Create programs with different color palettes.
- Use the `Pillow` module to produce image files of Mondrian art. You can learn about this module from Chapter 19 of *Automate the Boring Stuff with Python* at <https://automatetheboringstuff.com/2e/chapter19/>.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What error happens if you change `canvas[(x, y)] = WHITE` on line 41 to `canvas[(x, y)] = RED`?
2. What happens if you change `print(' ', end='')` on line 176 to `print('A', end='')`?

#48

MONTY HALL PROBLEM

The Monty Hall Problem illustrates a surprising fact of probability. The problem is loosely based on the old game show *Let's Make a Deal* and its host, Monty Hall. In the Monty Hall Problem, you can pick one of three doors. Behind one door is a prize: a new car. Each of the other two doors opens onto a worthless goat. Say you pick Door #1. Before the door you choose is opened, the host opens another door (either #2 or #3), which leads to a goat. You can choose to either open the door you originally picked or switch to the other unopened door.

It may seem like it doesn't matter if you switch or not, but your odds do improve if you switch doors! This program demonstrates the Monty Hall problem by letting you do repeated experiments.

To understand why your odds improve, consider a version of the Monty Hall Problem with one thousand doors instead of three. You pick one door, and then the host opens 998 doors, which all reveal goats. The only two

doors that are unopened are the one you selected and one other door. If you correctly picked the car door to begin with (a 1 in a 1,000 chance), then the host left a random goat door closed. If you picked a goat door (a 999 in a 1,000 chance), the host specifically chose the car door to leave closed. The choice of which doors to open isn't random; the host knows to leave the car door closed. It's almost certain that you didn't pick the car door to begin with, so you should switch to the other door.

Another way to think of it is that you have 1,000 boxes and one box contains a prize. You guess which box the prize is in and the host puts it in your hands. Do you think the prize is in your box or one of the 999 other boxes? You don't need the host to open 998 of the 999 boxes that don't contain a prize; the amount of choice is the same as with the 1,000 doors. The odds that you guessed correctly in the beginning are 1 in 1,000, while the odds that you did not (and that the prize is in one of the other boxes) is a near certain 999 in 1,000.

More information about the Monty Hall Problem can be found at https://en.wikipedia.org/wiki/Monty_Hall_problem.

The Program in Action

When you run *montyhall.py*, the output will look like this:

```

```
--snip--
```

How It Works

The multiline strings for the ASCII-art doors are stored in several constant variables, such as `ALL_CLOSED`, `FIRST_GOAT`, and `FIRST_CAR_OTHERS_GOAT`. The code that uses these constants, like `print(FIRST_GOAT)` on line 125, stays the same even if we update the graphics. By placing the multiline strings together toward the top of the source code file, we'll have an easier time comparing them to make sure the graphics are consistent.

```

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `doorThatHasCar = random.randint(1, 3)` on line 100 to `doorThatHasCar = 1`?
2. What happens if you replace lines 124 to 129 with `print([FIRST_GOAT, SECOND_GOAT, THIRD_GOAT][showGoatDoor - 1])`?

49

MULTIPLICATION TABLE

This program generates a multiplication table from 0×0 to 12×12 . While simple, it provides a useful demonstration of nested loops.

The Program in Action

When you run *multiplicationtable.py*, the output will look like this:

```
Multiplication Table, by Al Sweigart al@inventwithpython.com
| 0 1 2 3 4 5 6 7 8 9 10 11 12
-----
0| 0 0 0 0 0 0 0 0 0 0 0 0 0
1| 0 1 2 3 4 5 6 7 8 9 10 11 12
2| 0 2 4 6 8 10 12 14 16 18 20 22 24
3| 0 3 6 9 12 15 18 21 24 27 30 33 36
4| 0 4 8 12 16 20 24 28 32 36 40 44 48
5| 0 5 10 15 20 25 30 35 40 45 50 55 60
6| 0 6 12 18 24 30 36 42 48 54 60 66 72
7| 0 7 14 21 28 35 42 49 56 63 70 77 84
8| 0 8 16 24 32 40 48 56 64 72 80 88 96
9| 0 9 18 27 36 45 54 63 72 81 90 99 108
10| 0 10 20 30 40 50 60 70 80 90 100 110 120
11| 0 11 22 33 44 55 66 77 88 99 110 121 132
12| 0 12 24 36 48 60 72 84 96 108 120 132 144
```

How It Works

Line 9 prints the top row of the table. Notice that it sets a large enough distance between the numbers to accommodate products that are a maximum of three digits long. Since this is a 12×12 multiplication table, this spacing can fit the largest product, 144. If you want to create a larger table, you may need to increase the spacing for the columns as well. Keep in mind that the standard terminal window is 80 columns wide and 24 rows tall, so you cannot create much larger multiplication tables without having the rows wrap around the right edge of the window.

1. What happens if you change `range(0, 13)` on line 13 to `range(0, 80)`?
2. What happens if you change `range(0, 13)` on line 13 to `range(0, 100)`?

#50

NINETY-NINE BOTTLES

“Ninety-Nine Bottles” is a folk song of undetermined origin known for its length and repetitiveness. The lyrics go, “Ninety-nine bottles of milk on the wall, ninety-nine bottles of milk. Take one down, pass it around, ninety-eight bottles of milk on the wall.” As the lyrics repeat, the number of bottles falls from ninety-eight to ninety-seven, then from ninety-seven to ninety-six, until it reaches zero: “One bottle of milk on the wall, one bottle of milk. Take it down, pass it around, no more bottles of milk on the wall!”

Luckily for us, computers are excellent at performing repetitive tasks, and this program reproduces all of the lyrics programmatically. An extended version of this program is in Project 51, “niNety-niinE BoOttels.”

The Program in Action

When you run *ninety-ninebottles.py*, the output will look like this:

Ninety-Nine Bottles, by Al Sweigart al@inventwithpython.com

```
(Press Ctrl-C to quit.)
99 bottles of milk on the wall,
99 bottles of milk,
Take one down, pass it around,
98 bottles of milk on the wall!

98 bottles of milk on the wall,
98 bottles of milk,
Take one down, pass it around,
97 bottles of milk on the wall!
--snip--
```

How It Works

The repetition in this song makes it easy to use a `for` loop (from lines 20 to 30) to display the first 98 stanzas. However, the last stanza has some minor differences and requires separate code to display (lines 33 to 39). This is because the last line, 'No more bottles of milk on the wall!', deviates from the line repeated in the loop, and because the word “bottle” is singular rather than plural.

```

11. print()
12. print('(Press Ctrl-C to quit.)')
13.
14. time.sleep(2)
15.
16. bottles = 99 # This is the starting number of bottles.
17. PAUSE = 2 # (!) Try changing this to 0 to see the full song at once.
18.
19. try:
20.     while bottles > 1: # Keep looping and display the lyrics.
21.         print(bottles, 'bottles of milk on the wall,')
22.         time.sleep(PAUSE) # Pause for PAUSE number of seconds.
23.         print(bottles, 'bottles of milk,')
24.         time.sleep(PAUSE)
25.         print('Take one down, pass it around,')
26.         time.sleep(PAUSE)
```

```
27.         bottles = bottles - 1 # Decrease the number of bottles by one.
28.         print(bottles, 'bottles of milk on the wall!')
29.         time.sleep(PAUSE)
30.         print() # Print a newline.
31.
32.         # Display the last stanza:
33.         print('1 bottle of milk on the wall,')
34.         time.sleep(PAUSE)
35.         print('1 bottle of milk,')
36.         time.sleep(PAUSE)
37.         print('Take it down, pass it around,')
38.         time.sleep(PAUSE)
39.         print('No more bottles of milk on the wall!')
40. except KeyboardInterrupt:
41.     sys.exit() # When Ctrl-C is pressed, end the program.
```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Create a program for the repetitive song “The Twelve Days of Christmas.”
- Create programs for other cumulative songs. You can find a list of them at https://en.wikipedia.org/wiki/Cumulative_song.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `bottles = bottles - 1` on line 27 to `bottles = bottles - 2`?
2. What happens if you change `while bottles > 1:` on line 20 to `while bottles < 1:`?

#51

NINETY-NNIINE BOOTTELS

In this version of the song “Ninety-Nine Bottles,” the program introduces small imperfections in each stanza by either removing a letter, swapping the casing of a letter, transposing two letters, or doubling a letter.

As the song continues to play, these mutations add up, resulting in a very silly song. It’s a good idea to try Project 50, “Ninety-Nine Bottles,” before attempting this one.

The Program in Action

When you run `ninetyninebottles2.py`, the output will look like this:

```
niNety-nniinE BoOttels, by Al Sweigart al@inventwithpython.com
--snip--
99 bottles of milk on the wall,
99 bottles of milk,
Take one down, pass it around,
98 bottles of milk on the wall!

98 bottles of milk on the wall,
98 bottles of milk,
Take one d wn, pass it around,
97 bottles of milk on the wall!

97 bottles of milk on the wall,
97 bottels of milk,
Take one d wn, pass it around,
96 bottles of milk on the wall!
--snip--
75b otlte of mIl on teh wall,
75 ottels f milk,
Take one d wn, pass it ar und,
74 bbOttels of milk on t e wall!
--snip--
1 otlE t of iml oo nteh lall,
1 o Tle FF FmMLIIkk,
Taake on d wn, pAasSs itt au nn d,
No more bottles of milk on the wall!
```

How It Works

String values in Python are *immutable*, meaning they cannot be changed. If the string 'Hello' is stored in a variable called `greeting`, the code `greeting = greeting + ' world!'` doesn't actually change the 'Hello' string. Rather, it creates a new string, 'Hello world!', to replace the 'Hello' string in `greeting`. The technical reasons for this are beyond the scope of this book, but it's important to understand the distinction, because it means code like `greeting[0] = 'h'` isn't allowed, since strings are immutable. However, since lists are mutable, we can create a list of single-character strings (as line 62 does), change the characters in the list, and then create a string from the list (line 85). This is how our program seemingly changes, or *mutates*, the strings containing the song lyrics.

-
1. `"""niNety-nniinE BoOttels of Mlik On teh wall`
 2. `By Al Sweigart al@inventwithpython.com`
 3. Print the full lyrics to one of the longest songs ever! The song
 4. gets sillier and sillier with each verse. Press Ctrl-C to stop.

77.         secondChar = line[charIndex + 1]
78.         line[charIndex] = secondChar
79.         line[charIndex + 1] = firstChar
80.     elif effect == 3: # Double a character.
81.         charIndex = random.randint(0, len(line) - 2)
82.         line.insert(charIndex, line[charIndex])
83.
84.         # Convert the line list back to a string and put it in lines:
85.         lines[lineNum] = ''.join(line)
86. except KeyboardInterrupt:
87.     sys.exit() # When Ctrl-C is pressed, end the program.

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Swap the order of two adjacent words, where a “word” is text separated by spaces.
- On rare occasions, have the song start counting upward for a few iterations.
- Change the case of an entire word.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `bottles = bottles - 1` on line 47 to `bottles = bottles - 2`?
2. What happens if you change `effect = random.randint(0, 3)` on line 64 to `effect = 0`?
3. What error happens if you delete or comment out `line = list(lines[lineNum])` on line 62?

#52

NUMERAL SYSTEM COUNTERS

We're used to counting in the decimal numeral system, which uses 10 digits: 0 through 9. This system likely developed because humans counted on their fingers, and most people have 10 fingers. But other number systems exist. Computers make use of *binary*, a numeral system with only two digits, 0 and 1. Programmers also sometimes use hexadecimal, which is a base-16 numeral system that uses the digits 0 to 9 but also extends into the letters *A* to *F*.

We can represent any number in any numeral system, and this program displays a range of numbers in decimal, binary, and hexadecimal.

The Program in Action

When you run *numeralsystems.py*, the output will look like this:

Numeral System Counters, by Al Sweigart al@inventwithpython.com

```
--snip--
Enter the starting number (e.g. 0) > 0
Enter how many numbers to display (e.g. 1000) > 20
DEC: 0  HEX: 0  BIN: 0
DEC: 1  HEX: 1  BIN: 1
DEC: 2  HEX: 2  BIN: 10
DEC: 3  HEX: 3  BIN: 11
DEC: 4  HEX: 4  BIN: 100
DEC: 5  HEX: 5  BIN: 101
DEC: 6  HEX: 6  BIN: 110
DEC: 7  HEX: 7  BIN: 111
DEC: 8  HEX: 8  BIN: 1000
DEC: 9  HEX: 9  BIN: 1001
DEC: 10  HEX: A  BIN: 1010
DEC: 11  HEX: B  BIN: 1011
DEC: 12  HEX: C  BIN: 1100
DEC: 13  HEX: D  BIN: 1101
DEC: 14  HEX: E  BIN: 1110
DEC: 15  HEX: F  BIN: 1111
DEC: 16  HEX: 10  BIN: 10000
DEC: 17  HEX: 11  BIN: 10001
DEC: 18  HEX: 12  BIN: 10010
DEC: 19  HEX: 13  BIN: 10011
```

How It Works

You can get the binary and hexadecimal representations of a number in Python by calling the `bin()` and `hex()` functions, respectively:

```
>>> bin(42)
'0b101010'
>>> hex(42)
'0x2a'
```

Convert these strings back into decimal integers by calling `int()` and supplying the base to convert from, like so:

```
>>> int('0b101010', 2)
42
>>> int('0x2a', 16)
42
```

Keep in mind that the binary and hexadecimal “numbers” returned by `bin()` and `hex()` are actually string values: `bin(42)` returns the string `'0b101010'` and `hex(42)` returns the string `'0x2a'`. In programming, it is convention to add a `0b` prefix to binary numbers and `0x` prefix to hexadecimal numbers.

That way, no one will confuse the binary number 10000 (the number 16 in decimal) with the decimal number “ten thousand.” The numeral systems program removes these prefixes before displaying the number.

```
1. """Numeral System Counters, by Al Sweigart al@inventwithpython.com
2. Shows equivalent numbers in decimal, hexadecimal, and binary.
3. View this code at https://nostarch.com/big-book-small-python-projects
4. Tags: tiny, math"""
5.
6.
7. print('Numeral System Counters, by Al Sweigart al@inventwithpython.com
8.
9. This program shows you equivalent numbers in decimal (base 10),
10. hexadecimal (base 16), and binary (base 2) numeral systems.
11.
12. (Ctrl-C to quit.)
13. '''
14.
15. while True:
16.     response = input('Enter the starting number (e.g. 0) > ')
17.     if response == '':
18.         response = '0' # Start at 0 by default.
19.         break
20.     if response.isdecimal():
21.         break
22.     print('Please enter a number greater than or equal to 0.')
23. start = int(response)
24.
25. while True:
26.     response = input('Enter how many numbers to display (e.g. 1000) > ')
27.     if response == '':
28.         response = '1000' # Display 1000 numbers by default.
29.         break
30.     if response.isdecimal():
31.         break
32.     print('Please enter a number.')
33. amount = int(response)
34.
35. for number in range(start, start + amount): # Main program loop.
36.     # Convert to hexadecimal/binary and remove the prefix:
37.     hexNumber = hex(number)[2:].upper()
38.     binNumber = bin(number)[2:]
39.
40.     print('DEC:', number, '    HEX:', hexNumber, '    BIN:', binNumber)
```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Enter a new row for *octal*, the base-8 number system, using Python’s `oct()` function.
- Search the internet for “number system conversion” to find out how to implement your own `bin()`, `oct()`, and `hex()` functions.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `hex(number)[2:].upper()` on line 37 to `hex(number)[2:]`?
2. What error do you cause if you change `int(response)` on line 33 to `response`?

#53

PERIODIC TABLE OF THE ELEMENTS

The periodic table of the elements organizes all known chemical elements into a single table. This program presents this table and lets the player access additional information about each element, such as its atomic number, symbol, melting point, and so on. I compiled this information from Wikipedia and stored it in a file called *periodictable.csv* that you can download from <https://inventwithpython.com/periodictable.csv>.

The Program in Action

When you run *periodictable.py*, the output will look like this:

Periodic Table of Elements

By Al Sweigart al@inventwithpython.com

Periodic Table of Elements

> 42

Atomic Number: 42

Symbol: Mo

Element: Molybdenum

Origin of name: Greek molýbdaina, 'piece of lead', from mólybdos, 'lead'

Group: 6

Period: 5

Atomic weight: 95.95(1) u

Density: 10.22 g/cm³

Melting point: 2896 K

Boiling point: 4912 K

Specific heat capacity: 0.251 J/(g*K)

Electronegativity: 2.16

Abundance in earth's crust: 1.2 mg/kg

Press Enter to continue...

--snip--

How It Works

A *.csv*, or *comma-separated values*, file is a text file that represents a primitive spreadsheet. Each line in the *.csv* file is a row, and commas separate the columns. For example, the first three lines in *periodictable.csv* look like this:

```
1,H,Hydrogen,"Greek elements hydro- and -gen, meaning 'water-forming"--snip--
2,He,Helium,"Greek hēlios, 'sun'",18,1,4.002602(2)[III][V],0.0001785--snip--
3,Li,Lithium,"Greek líthos, 'stone'",1,2,6.94[III][IV][V][VIII][VI],--snip--
```

Python's `csv` module makes it easy to import data from a *.csv* file and into a list of lists of strings, as lines 15 to 18 do. Lines 32 to 58 turn this list of lists into a dictionary so that the rest of the program can easily summon the information by an element's name or atomic number.

```

1. """Periodic Table of Elements, by Al Sweigart al@inventwithpython.com

```

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What bug do you cause if you change `response == 'Quit'` on line 81 to `response == 'quit'`?
2. What happens if you delete or comment out lines 53 and 55?

#54

PIG LATIN

Pig Latin is a word game that transforms English words into a parody of Latin. In Pig Latin, if a word begins with a consonant, the speaker removes this letter and puts it at the end, followed by “ay.” For example, “pig” becomes “igpay” and “latin” becomes “atinlay.” Otherwise, if the word begins with a vowel, the speaker simply adds “yay” to the end of it. For example, “elephant” becomes “elephantyay” and “umbrella” becomes “umbrellayay.”

The Program in Action

When you run *piglatin.py*, the output will look like this:

```
Igpay Atinlay (Pig Latin)
By Al Sweigart al@inventwithpython.com

Enter your message:
> This is a very serious message.
Isthay isyay ayay eryvay erioussay essagemay.
(Copied pig latin to clipboard.)
```

How It Works

The `englishToPigLatin()` function takes a string of English text and returns a string of its Pig Latin equivalent. The `main()` function only gets called if a user runs the program directly. You could also write your own Python programs, import *piglatin.py* with an `import piglatin` statement, then call `piglatin.englishToPigLatin()` to make use of the `englishToPigLatin()` function. This reuse technique can save you the time and effort required to reinvent this code yourself.

```

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `message.split()` on line 33 to `message`?
2. What happens if you change `('a', 'e', 'i', 'o', 'u', 'y')` on line 11 to `()`?
3. What happens if you change `('a', 'e', 'i', 'o', 'u', 'y')` on line 11 to `('A', 'E', 'I', 'O', 'U', 'Y')`?

#55

POWERBALL LOTTERY

The Powerball Lottery is an exciting way to lose small amounts of money. If you purchase a \$2 ticket, you can pick six numbers: five drawn from 1 to 69, and a sixth “Powerball” number drawn from 1 to 26. The order of the numbers doesn’t matter. If the lottery selects your six numbers, you win \$1.586 billion dollars! Except you won’t win, because your odds are 1 in 292,201,338. But if you spent \$200 on 100 tickets, your odds would be . . . 1 in 2,922,013. You won’t win that either, but at least you’ll lose 100 times as much money. The more you like losing money, the more fun the lottery is!

To help you visualize how often you won’t win the lottery, this program simulates up to one million Powerball drawings and then compares them with the numbers you picked. Now you can have all the excitement of losing the lottery without spending money.

Fun fact: every set of six numbers is just as likely to win as any other. So the next time you want to buy a lottery ticket, pick the numbers 1, 2, 3, 4, 5, and 6. Those numbers are just as likely to come up as a more complex set.

The Program in Action

When you run `powerballlottery.py`, the output will look like this:

```
Powerball Lottery, by Al Sweigart al@inventwithpython.com

Each powerball lottery ticket costs $2. The jackpot for this game
is $1.586 billion! It doesn't matter what the jackpot is, though,
because the odds are 1 in 292,201,338, so you won't win.

This simulation gives you the thrill of playing without wasting money.

Enter 5 different numbers from 1 to 69, with spaces between
each number. (For example: 5 17 23 42 50 51)
> 1 2 3 4 5
Enter the powerball number from 1 to 26.
> 6
How many times do you want to play? (Max: 1000000)
> 1000000
It costs $2000000 to play 1000000 times, but don't
worry. I'm sure you'll win it all back.
Press Enter to start...
The winning numbers are: 12 29 48 11 4 and 13 You lost.
The winning numbers are: 54 39 3 42 16 and 12 You lost.
The winning numbers are: 56 4 63 23 38 and 24 You lost.
--snip--
The winning numbers are: 46 29 10 62 17 and 21 You lost.
The winning numbers are: 5 20 18 65 30 and 10 You lost.
The winning numbers are: 54 30 58 10 1 and 18 You lost.
You have wasted $2000000
Thanks for playing!
```

How It Works

The output from this program looks fairly uniform because the `allWinningNums.ljust(21)` code on line 109 pads the numbers with enough spaces to take up 21 columns, no matter how many digits the winning numbers have. This makes the “You lost.” text always appear in the same place on the screen, so it remains readable even as the program quickly outputs several lines.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `possibleNumbers[0:5]` on line 100 to numbers and `random.randint(1, 26)` on line 101 to `powerball`?
2. What error do you get if you delete or comment out `possibleNumbers = list(range(1, 70))` on line 96?

#56

PRIME NUMBERS

A *prime number* is a number that is evenly divisible only by one and itself. Prime numbers have a variety of practical applications, but no algorithm can predict them; we must calculate them one at a time. However, we do know that there is an infinite number of prime numbers to be discovered.

This program finds prime numbers through brute-force calculation. Its code is similar to Project 24, “Factor Finder.” (Another way to describe a prime number is that one and the number itself are its only factors.) You can find out more about prime numbers from https://en.wikipedia.org/wiki/Prime_number.

The Program in Action

When you run *primenumbers.py*, the output will look like this:

```
Prime Numbers, by Al Sweigart al@inventwithpython.com
--snip--
Enter a number to start searching for primes from:
(Try 0 or 1000000000000 (12 zeros) or another number.)
> 0
Press Ctrl-C at any time to quit. Press Enter to begin...
2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71,
73, 79, 83, 89, 97, 101, 103, 107, 109, 113, 127, 131, 137, 139, 149, 151,
157, 163, 167, 173, 179, 181, 191, 193, 197, 199, 211, 223, 227, 229, 233,
239, 241, 251, 257, 263, 269, 271, 277, 281, 283, 293, 307, 311, 313, 317,
331, 337, 347, 349, 353, 359, 367, 373, 379, 383, 389, 397, 401, 409, 419,

509, 521, 523, 541, 547, 557, 563, 569, 571, 577, 587, 593, 599, 601, 607,
613, 617, 619, 631, 641, 643, 647, --snip--
```

How It Works

The `isPrime()` function accepts an integer and returns `True` if it is a prime number. Otherwise, it returns `False`. Project 24 is worth studying if you're trying to understand this program. The `isPrime()` function essentially looks for any factors in the given number and returns `False` if it finds any.

The algorithm in this program can quickly find large prime numbers. The number one trillion has a mere 10 digits. But to find prime numbers that are as big as a googol (a one followed by 100 zeros), you need to use an advanced algorithm such as the Rabin-Miller primality test. Chapter 22 of my book *Cracking Codes with Python* (No Starch Press, 2018) has a Python implementation of this algorithm.

```

55.     except KeyboardInterrupt:
56.         sys.exit() # When Ctrl-C is pressed, end the program.

```

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What error do you get if you change `response.isdecimal()` on line 22 to `response.isnumeric()` and enter a non-number for the number from which to start searching for primes?
2. What happens if you change `number < 2` on line 38 to `number > 2`?
3. What happens if you change `number % i == 0` on line 46 to `number % i != 0`?

#57

PROGRESS BAR

A *progress bar* is a visual element that shows how much of a task has been completed. Progress bars are often used alongside downloading files or software installations. This project creates a `getProgressBar()` function that returns a progress bar string based on the arguments passed to it. It simulates a downloading file, but you can reuse the progress bar code in your own projects.

The Program in Action

When you run *progressbar.py*, the output will look like this:

```
Progress Bar Simulation, by Al Sweigart  
[██████████] 24.6% 1007/4098
```

How It Works

The progress bar relies on a certain trick that programs running in terminal windows can perform. Just as `\n` and `\t` are escape characters for newline and tab characters, respectively, `\b` is an escape character for backspace characters. If you “print” a backspace character, the text cursor will move to the left and erase the previously printed character. This only works for the current line the text cursor is on. If you run the code `print('Hello\b\b\b\b\bHowdy')`, Python will print the text “Hello,” move the text cursor back five spaces, and then print the text “Howdy.” The “Howdy” text will overwrite “Hello,” making it look as though you called “Howdy.”

We can use this technique to create an animated progress bar on a single line by printing one version of the bar, moving the text cursor back to the start, then printing an updated progress bar. This effect can generate any text animation without requiring a module such as `bext`, though it will be limited to taking up a single line in the terminal window.

Once you’ve created this program, you can display progress bars in your other Python programs by running `import progressbar` and printing the string returned from `progressbar.getProgressBar()`.

```

34.     bars and has progressed progress amount out of a total amount."""
35.
36.     progressBar = '' # The progress bar will be a string value.
37.     progressBar += '[' # Create the left end of the progress bar.
38.
39.     # Make sure that the amount of progress is between 0 and total:
40.     if progress > total:
41.         progress = total
42.     if progress < 0:
43.         progress = 0
44.
45.     # Calculate the number of "bars" to display:
46.     numberOfBars = int((progress / total) * barWidth)
47.
48.     progressBar += BAR * numberOfBars # Add the progress bar.
49.     progressBar += ' ' * (barWidth - numberOfBars) # Add empty space.
50.     progressBar += ']' # Add the right end of the progress bar.
51.
52.     # Calculate the percentage complete:
53.     percentComplete = round(progress / total * 100, 1)
54.     progressBar += ' ' + str(percentComplete) + '%' # Add percentage.
55.
56.     # Add the numbers:
57.     progressBar += ' ' + str(progress) + '/' + str(total)
58.
59.     return progressBar # Return the progress bar string.
60.
61.
62. # If the program is run (instead of imported), run the game:
63. if __name__ == '__main__':
64.     main()

```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Create a one-line animation of a spinner that alternates between the characters |, /, -, and \ to produce a rotating effect.
- Create a program that can display a scrolling marquee of text moving from left to right.
- Create a one-line animation that displays a set of four equal signs moving back and forth as a single unit, similar to the red scanning light on the robot car from the TV show *Knight Rider* or the Cylon robot face from the TV show *Battlestar Galactica*.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you delete or comment out `print('\b' * len(barStr), end='', flush=True)` on line 29?
2. What happens if you switch the order of lines 48 and 49?
3. What happens if you change `round(progress / total * 100, 1)` on line 53 to `round(progress / total * 100)`?

#58

RAINBOW

Rainbow is a simple program that shows a colorful rainbow traveling back and forth across the screen. The program makes use of the fact that when new lines of text appear, the existing text scrolls up, causing it to look like it's moving. This program is good for beginners, and it's similar to Project 15, "Deep Cave."

The Program in Action

Figure 58-1 shows what the output will look like when you run `rainbow.py`.

Figure 58-1: The zigzag output of the rainbow, which is in color on the screen

How It Works

This program continuously prints the same rainbow pattern. What changes is the number of space characters printed to the left of it. Increasing this number moves the rainbow to the right, and decreasing it moves the rainbow to the left. The `indent` variable keeps track of the number of spaces. The `indentIncreasing` variable is set to `True` to note that `indent` should increase until it reaches 60, at which point it changes to `False`. The rest of the code decreases the number of spaces. Once it reaches 0, it changes back to `True` again to repeat the zigzag of the rainbow.

1. What happens if you change False on line 44 to True?
2. What happens if you change the argument to all `bext.fg()` calls to 'random'?

#59

ROCK PAPER SCISSORS

In this version of the two-player hand game also known as Rochambeau or jan-ken-pon, the player faces off against the computer.

You can pick either rock, paper, or scissors. Rock beats scissors, scissors beats paper, and paper beats rock. This program adds some brief pauses for suspense.

For a variation of this game, see Project 60, “Rock Paper Scissors (Always-Win Version).”

The Program in Action

When you run *rockpaperscissors.py*, the output will look like this:

```
Rock, Paper, Scissors, by Al Sweigart al@inventwithpython.com
- Rock beats scissors.
- Paper beats rocks.
- Scissors beats paper.

0 Wins, 0 Losses, 0 Ties
Enter your move: (R)ock (P)aper (S)cissors or (Q)uit
> r
ROCK versus...
1...
2...
3...
SCISSORS
You win!
1 Wins, 0 Losses, 0 Ties
Enter your move: (R)ock (P)aper (S)cissors or (Q)uit
--snip--
```

How It Works

The game logic for Rock Paper Scissors is fairly straightforward, and we implement it here with `if-elif` statements. To add a bit of suspense, lines 45 to 51 count down before revealing the opponent's move, with brief pauses between counts. This gives the player a period in which their excitement builds about the results of the game. Without this pause, the results would appear as soon as the player entered their move—a bit anticlimactic. It doesn't take a lot of code to improve the user experience for the player.

```

48.     print('2...')
49.     time.sleep(0.25)
50.     print('3...')
51.     time.sleep(0.25)
52.
53.     # Display what the computer chose:
54.     randomNumber = random.randint(1, 3)
55.     if randomNumber == 1:
56.         computerMove = 'ROCK'
57.     elif randomNumber == 2:
58.         computerMove = 'PAPER'
59.     elif randomNumber == 3:
60.         computerMove = 'SCISSORS'
61.     print(computerMove)
62.     time.sleep(0.5)
63.
64.     # Display and record the win/loss/tie:
65.     if playerMove == computerMove:
66.         print('It\'s a tie!')
67.         ties = ties + 1
68.     elif playerMove == 'ROCK' and computerMove == 'SCISSORS':
69.         print('You win!')
70.         wins = wins + 1
71.     elif playerMove == 'PAPER' and computerMove == 'ROCK':
72.         print('You win!')
73.         wins = wins + 1
74.     elif playerMove == 'SCISSORS' and computerMove == 'PAPER':
75.         print('You win!')
76.         wins = wins + 1

```

```
77.     elif playerMove == 'ROCK' and computerMove == 'PAPER':
78.         print('You lose!')
79.         losses = losses + 1
80.     elif playerMove == 'PAPER' and computerMove == 'SCISSORS':
81.         print('You lose!')
82.         losses = losses + 1
83.     elif playerMove == 'SCISSORS' and computerMove == 'ROCK':
84.         print('You lose!')
85.         losses = losses + 1
```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Add “Lizard” and “Spock” moves to the game. Lizard poisons Spock and eats paper, but is crushed by rock and decapitated by scissors. Spock breaks scissors and vaporizes rock, but is poisoned by lizard and disproved by paper.
- Allow the player to win a point for each victory and lose a point for each defeat. Upon winning, the player can also take “double or nothing” risks to possibly win 2, 4, 8, 16, and an increasing number of points in subsequent rounds.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What error do you get if you change `random.randint(1, 3)` on line 54 to `random.randint(1, 300)`?
2. What happens if you change `playerMove == computerMove` on line 65 to `True`?

#60

ROCK PAPER SCISSORS (ALWAYS-WIN VERSION)

This variant of Rock Paper Scissors is identical to Project 59, “Rock Paper Scissors,” except the player will always win. The code selecting the computer’s move is set so that it always chooses the losing move. You can offer this game to your friends, who may be excited when they win . . . at first. See how long it takes before they catch on to the fact that the game is rigged in their favor.

The Program in Action

When you run `rockpaperscissorsalwayswin.py`, the output will look like this:

```
Rock, Paper, Scissors, by Al Sweigart al@inventwithpython.com
- Rock beats scissors.
- Paper beats rocks.
- Scissors beats paper.

0 Wins, 0 Losses, 0 Ties
Enter your move: (R)ock (P)aper (S)cissors or (Q)uit
> p
PAPER versus...
1...
2...
3...
ROCK
You win!
1 Wins, 0 Losses, 0 Ties
Enter your move: (R)ock (P)aper (S)cissors or (Q)uit
> s
SCISSORS versus...
1...
2...
3...
PAPER
You win!
2 Wins, 0 Losses, 0 Ties
--snip--
SCISSORS versus...
1...
2...
3...
PAPER
You win!
413 Wins, 0 Losses, 0 Ties
Enter your move: (R)ock (P)aper (S)cissors or (Q)uit
--snip--
```

How It Works

You may notice that this version of the program is shorter than Project 59. This makes sense: when you don't have to randomly generate a move for the computer and compute the results of the game, you can remove quite a bit of code from the original. There are also no variables to track the number of losses and ties, since these would be zero all the time anyway.

42.     print('1...')
43.     time.sleep(0.25)
44.     print('2...')
45.     time.sleep(0.25)
46.     print('3...')
47.     time.sleep(0.25)
48.
49.     # Display what the computer chose:
50.     if playerMove == 'R':
51.         print('SCISSORS')
52.     elif playerMove == 'P':
53.         print('ROCK')
54.     elif playerMove == 'S':
55.         print('PAPER')
56.
57.     time.sleep(0.5)
58.
59.     print('You win!')
60.     wins = wins + 1

```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Add “Lizard” and “Spock” moves to the game. Lizard poisons Spock and eats paper, but is crushed by rock and decapitated by scissors. Spock breaks scissors and vaporizes rock, but is poisoned by lizard and disproved by paper.
- Allow the player to win a point for each victory. Upon winning, the player can also take “double or nothing” risks to possibly win 2, 4, 8, 16, and an increasing number of points.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you delete or comment out lines 33 to 57?
2. What happens if you change `input('> ').upper()` on line 22 to `input('> ')`?

#61

ROT13 CIPHER

The ROT13 cipher, one of the simplest encryption algorithms, stands for “rotate 13 spaces.” The cypher represents the letters *A* to *Z* as the numbers 0 to 25 in such a way that the encrypted letter is 13 spaces from the plain-text letter: *A* becomes *N*, *B* becomes *O*, and so on. The encryption process is identical to the decryption process, making it trivial to program. However, the encryption is also trivial to break. Because of this, you’ll most often find ROT13 used to conceal non-sensitive information, such as spoilers or trivia answers, so it’s not read unintentionally. More information about the ROT13 cipher can be found at <https://en.wikipedia.org/wiki/ROT13>. If you’d like to learn about ciphers and code breaking more generally, you can read my book *Cracking Codes with Python* (No Starch Press, 2018; <https://nostarch.com/crackingcodes/>).

The Program in Action

When you run `rot13cipher.py`, the output will look like this:

```
ROT13 Cipher, by Al Sweigart al@inventwithpython.com
```

```
Enter a message to encrypt/decrypt (or QUIT):
```

```
> Meet me by the rose bushes tonight.
```

```
The translated message is:
```

```
Zrrg zr ol gur ebfr ohfurf gbavtug.
```

```
(Copied to clipboard.)
```

```
Enter a message to encrypt/decrypt (or QUIT):
```

```
--snip--
```

How It Works

ROT13 shares a lot of code with Project 6, “Caesar Cipher,” although it’s much simpler because it always uses the key 13. Since the same code performs both the encryption and decryption (lines 27 to 39), there’s no need to ask the player which mode they want to use.

One difference is that this program maintains the casing of the original message instead of automatically converting the message to uppercase. For example, “Hello” encrypts to “Uryyb,” whereas “HELLO” encrypts to “URYYB.”

```

1. What happens if you change `character.isupper()` on line 29 to `character.islower()`?
2. What happens if you change `print(translated)` on line 43 to `print(message)`?

62

ROTATING CUBE

This project features an animation of a 3D cube rotating using trigonometric functions. You can adapt the 3D point rotation math and the `line()` function in your own animation programs.

Although the block text characters we'll use to draw the cube don't look like thin, straight lines, this kind of drawing is called a *wireframe model* because it renders only the edges of an object's surfaces. Figure 62-1 shows the wireframe model for a cube and an icosphere, a rough sphere made of triangles.

Figure 62-1: The wireframe models for a cube (left) and an icosphere (right)

The Program in Action

Figure 62-2 shows what the output will look like when you run *rotatingcube.py*.

Figure 62-2: The wireframe cube that the program draws to the screen

How It Works

This algorithm has two main parts: the `line()` function and the `rotatePoint()` function. The cube has eight points, one for each corner. The program stores these corners as (x, y, z) tuples in the `CUBE_CORNERS` list. These points also define the connections for the cube's edge lines. When all the points rotate in the same direction by the same amount, they give the illusion of a cube rotating.

```

215.     sys.exit() # When Ctrl-C is pressed, end the program.
```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Modify `CUBE_CORNERS` and the tuple on line 184 to create different wire-frame models such as a pyramid and a flat hexagon.
- Increase the coordinates of `CUBE_CORNERS` by 1.5 so that the cube revolves around the center of the screen, rather than rotating around its own center.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you delete or comment out lines 208 to 211?
2. What happens if you change the tuples on line 184 to `<((0, 1), (1, 3), (3, 2), (2, 0), (0,4), (4, 5), (5, 1))>`?

#63

ROYAL GAME OF UR

The Royal Game of Ur is a 5,000-year-old game from Mesopotamia. Archeologists rediscovered the game in the Royal Cemetery at Ur, in modern-day southern Iraq, during excavations between 1922 and 1934. The rules were reconstructed from the game board (shown in Figure 63-1) and a Babylonian clay tablet, and they're similar to Parcheesi. You'll need both luck and skill to win.

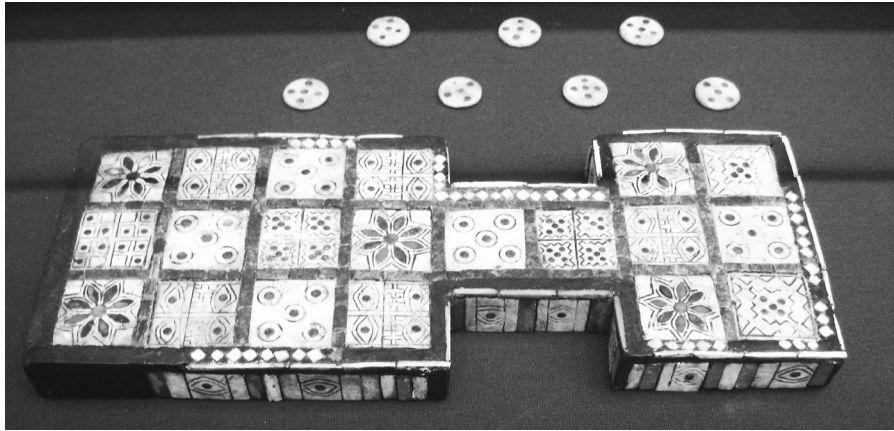

Figure 63-1: One of the five game boards found in the Royal Cemetery at Ur

Two players each begin with seven tokens in their home, and the first player to move all seven to the goal is the winner. Players take turns throwing four dice. These dice are four-pointed pyramid shapes called tetrahedrons. Each die has two marked points, giving an even chance that the dice come up marked or unmarked. Instead of dice, our game uses coins whose heads act as the marked point. The player can move a token one space for each marked point that comes up. This means they can move a single token between zero and four spaces, though they're most likely to roll two spaces.

The tokens travel along the path indicated in Figure 63-2. Only one token may exist on a space at a time. If a token lands on an opponent's token while in the shared middle path, the opponent's token is sent back home. If a token lands on the middle flower square, it is safe from being landed on. If a token lands on any of the other four flower tiles, the player gets to roll again. Our game will represent the tokens with the letters *X* and *O*.

Figure 63-2: The path each player's token takes from their home to their goal

A video featuring YouTuber Tom Scott and British Museum curator Irving Finkel discussing the Royal Game of Ur can be found at <https://www.youtube.com/watch?v=WZskjLq040I>.

The Program in Action

When you run *royalgameofur.py*, the output will look like this:

```

           ^               v
          Home             Goal
          000000          .....
```

```
It is 0's turn. Press Enter to flip...
Flips: H-H-H-H Select token to move 4 spaces: home quit
> home
0 landed on a flower space and gets to go again.
Press Enter to continue...
--snip--
```

How It Works

Like in Project 43, “Mancala,” the spaces on the ASCII-art game board are labeled with the letters *a* through *t*. After rolling, the player can select a space that contains their token to move that token, or they can select home to begin moving a token from their home to the board. The program represents the board as a dictionary with the keys ‘a’ to ‘t’ and the values of ‘X’ and ‘0’ for the tokens (or ‘ ’ for a blank space).

Additionally, this dictionary has keys ‘x_home’, ‘o_home’, ‘x_goal’, and ‘o_goal’, and the values for these keys are seven-character strings that represent how full the homes and goals are. The ‘X’ or ‘0’ characters in these strings represent tokens at the home or goal, and ‘.’ represents an empty slot. The `displayBoard()` function displays these seven-character strings on the screen.

```

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `nextTrackSpaceIndex == len(track) - 1` on line 152 to `nextTrackSpaceIndex == 1`?
2. What happens if you change `result = random.randint(0, 1)` on line 106 to `result = 1`?
3. What error do you cause if you change `board = {X_HOME: 7, X_GOAL: 0, O_HOME: 7, O_GOAL: 0}` on line 184 to `board = {}`?

#64

SEVEN-SEGMENT DISPLAY MODULE

A seven-segment display is a type of LCD component used to display numbers in pocket calculators, microwave ovens, and other small electronic devices. Through different combinations of seven line-shaped segments in an LCD, a seven-segment display can represent the digits 0 through 9. They look like this:

The benefit of this program is that other programs can import it as a module. Project 14, “Countdown,” and Project 19, “Digital Clock,” import the *sevseg.py* file so they can use its `getSevSegStr()` function. You can find more information about seven-segment displays and other variations at https://en.wikipedia.org/wiki/Seven-segment_display.

The Program in Action

Even though it's a module, *sevseg.py* outputs a sample demo of the digits it produces when you run the program directly. The output will look like this:

This module is meant to be imported rather than run.

For example, this code:

```
import sevseg
myNumber = sevseg.getSevSegStr(42, 3)
print(myNumber)
```

Will print 42, zero-padded to three digits:

```
  | | |
  | | |
  | | |
```

How It Works

The `getSevSegStr()` function first creates a list of three strings. The strings represent the top, middle, and bottom row of the numeric digits. Lines 27 to 75 have a long list of `if-elif` statements for each digit (and the decimal point and minus sign) that concatenates the rows of each digit to these strings. These three strings are joined together with newlines on line 84 so that the function returns a single multiline string suitable to pass to `print()`.

70.         rows[1] += '|_|'
71.         rows[2] += '|_|'
72.     elif numeral == '9': # Render the 9.
73.         rows[0] += ' _ '
74.         rows[1] += '|_|'
75.         rows[2] += ' _| '
76.
77.     # Add a space (for the space in between numerals) if this
78.     # isn't the last numeral:
79.     if i != len(number) - 1:
80.         rows[0] += ' '
81.         rows[1] += ' '
82.         rows[2] += ' '
83.

```

```

84.     return '\n'.join(rows)
85.
86.
87. # If this program isn't being imported, display the numbers 00 to 99.
88. if __name__ == '__main__':
89.     print('This module is meant to be imported rather than run.')
90.     print('For example, this code:')
91.     print('     import sevseg')
92.     print('     myNumber = sevseg.getSevSegStr(42, 3)')
93.     print('     print(myNumber)')
94.     print()
95.     print('...will print 42, zero-padded to three digits:')
96.     print('   _   _   ')
97.     print('| |_| | |_| |_|')
98.     print('| |_| | |_| |_|')

```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Create new fonts for numbers, such as using five rows and the block character string returned by `chr(9608)`.
- Look at the Wikipedia article for seven-segment displays to find out how to display letters and then add those to *sevseg.py*.
- Learn about sixteen-segment displays from https://en.wikipedia.org/wiki/Sixteen-segment_display and create a *sixteenseg.py* module to generate numbers in that style.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change the single-space strings on lines 80, 81, and 82 to empty strings?
2. What happens if you change the `minWidth=0` default argument on line 18 to `minWidth=8`?

#65

SHINING CARPET

The Shining, a 1980 psychological horror film directed by Stanley Kubrick, takes place at the haunted Overlook Hotel. The hotel carpet's hexagonal design became an iconic part of this famous movie. The carpet features alternating and interlocking hexagons whose mesmerizing effect is well-suited for such an unnerving film. The short program in this project, similar to Project 35, "Hex Grid," prints this repetitive pattern on the screen.

Note that this program uses raw strings, which prefix the opening quote with a lowercase `r`, so that the backslashes in the string aren't interpreted as escape characters.

The Program in Action

When you run *shiningcarpet.py*, the output will look like this:

How It Works

The creation of a program like this (or the similar Project 35) doesn't begin with coding but rather just drawing tessellating shapes in a text editor. Once you've written out the pattern, you can cut it down to the smallest unit to be tiled:

After you've copied and pasted this text into the source code, you can write the rest of the program around it. Software is not just a matter of sitting down and writing code from beginning to end. Every professional software developer goes through several iterations of tinkering, experimentation, and debugging. The end result may be just nine lines of code, but a small program doesn't necessarily imply that a small amount of effort went into making it.

-
1. `"""Shining Carpet, by Al Sweigart al@inventwithpython.com`
 2. `Displays a tessellation of the carpet pattern from The Shining.`
 3. `View this code at https://nostarch.com/big-book-small-python-projects`
 4. `Tags: tiny, beginner, artistic"""`
 5.
 6. `# Set up the constants:`

```

7. X_REPEAT = 6 # How many times to tessellate horizontally.
8. Y_REPEAT = 4 # How many times to tessellate vertically.
9.
10. for i in range(Y_REPEAT):
11.     print(r'\ \ \ \ /' * X_REPEAT)
12.     print(r'\ \ \ \ /' * X_REPEAT)
13.     print(r'\ \ \ \ /' * X_REPEAT)
14.     print(r'/ / / / \ ' * X_REPEAT)
15.     print(r'/ / / / \ ' * X_REPEAT)
16.     print(r'_ / / / \ _ ' * X_REPEAT)

```

Exploring the Program

For practice, try creating patterns such as the following:

```

_ | _ | _ | _ | _ | _ | _ | _ | _ | _ | _ | _ | _ | _ | _ | _ |
_ | _ | _ | _ | _ | _ | _ | _ | _ | _ | _ | _ | _ | _ | _ |

#66

SIMPLE SUBSTITUTION CIPHER

The Simple Substitution Cipher substitutes one letter for another. Since there are 26 possible substitutions for the letter *A*, 25 possible substitutions for *B*, 24 for *C*, and so on, the total number of possible keys is $26 \times 25 \times 24 \times 23 \times \dots \times 1$, or 403,291,461,126,605,635,584,000,000 keys! That's far too many keys for even a supercomputer to brute force, so the code-breaking method used in Project 7, "Caesar Hacker," can't be used against the simple cipher. Unfortunately, devious attackers can take advantage of known weakness to break the code. If you'd like to learn more about ciphers and code breaking, you can read my book *Cracking Codes with Python* (No Starch Press, 2018; <https://nostarch.com/crackingcodes/>).

The Program in Action

When you run *simplesubcipher.py*, the output will look like this:

```
Simple Substitution Cipher, by Al Sweigart
A simple substitution cipher has a one-to-one translation for each
symbol in the plaintext and each symbol in the ciphertext.
Do you want to (e)ncrypt or (d)ecrypt?
> e
Please specify the key to use.
Or enter RANDOM to have one generated for you.
> random
The key is WNOMTRCEHDXBFVSLKAGZIPYJQU. KEEP THIS SECRET!
Enter the message to encrypt.
> Meet me by the rose bushes tonight.
The encrypted message is:
Fttz ft nq zet asgt nigetg zsvhcez.
Full encrypted text copied to clipboard.
```

```
Simple Substitution Cipher, by Al Sweigart
A simple substitution cipher has a one-to-one translation for each
symbol in the plaintext and each symbol in the ciphertext.
Do you want to (e)ncrypt or (d)ecrypt?
> d
Please specify the key to use.
> WNOMTRCEHDXBFVSLKAGZIPYJQU
Enter the message to decrypt.
> Fttz ft nq zet asgt nigetg zsvhcez.
The decrypted message is:
Meet me by the rose bushes tonight.
Full decrypted text copied to clipboard.
```

How It Works

The position of each of the key's 26 letters corresponds to the letter of the alphabet at that same position:

```
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓
WNOMTRCEHDXBFVSLKAGZIPYJQU
```

Figure 66-1: How the letters of the alphabet encrypt with a key that begins with WNOM. To decrypt, replace letters at the bottom with the corresponding letters above them.

With this key, the letter *A* encrypts to *W* (and *W* decrypts to *A*), the letter *B* encrypts to *N*, and so on. The `LETTERS` and `key` variables are assigned to `charsA` and `charsB` (or the other way around if decrypting). Any message characters in `charsA` are substituted with the corresponding character in `charsB` to produce the final translated message.

1. What happens if you delete or comment out `random.shuffle(key)` on line 122 and enter `RANDOM` for the key?
2. What happens if you extend the `LETTERS` string on line 16 to become `'ABCDEFGHIJKLMNOPQRSTUVWXYZ1234567890'`?

67

SINE MESSAGE

This program displays a message of the user's choice in a wavy pattern as the text scrolls up. It accomplishes this effect with `math.sin()`, which implements the trigonometric sine wave function. But even if you don't understand the math, this program is rather short and easy to copy.

The Program in Action

When you run *sinemessage.py*, the output will look like this:

Sine Message, by Al Sweigart al@inventwithpython.com
(Press Ctrl-C to quit.)

What message do you want to display? (Max 39 chars.)

```

How It Works

The `math.sin()` function in Python's `math` module takes an argument, which we'll call x , and returns another number called the *sine of x* . Several mathematical applications use the sine function; in our program, its purpose is merely to create a neat wave effect. We pass a variable named `step` to `math.sin()`. This variable starts at 0 and increases by 0.25 on each iteration of the main program loop.

We'll use the return value of `math.sin()` to figure out how many spaces of padding we should print on either side of the user's message. Since `math.sin()` returns a floating point number between -1.0 and 1.0, but the minimum amount of padding we want is zero, not a negative value, line 31 adds 1 to the return value of `math.sin()`, making the effective range 0.0 to 2.0. We'll certainly need more than zero to two spaces, so line 31 multiplies this number by a variable named `multiplier` to increase the amount of padding. The product of this multiplication is the number of spaces of padding to add to the left side before printing the user's message.

The result is the waving message animation you see when you run the program.

```

5.
6. import math, shutil, sys, time
7.
8. # Get the size of the terminal window:
9. WIDTH, HEIGHT = shutil.get_terminal_size()
10. # We can't print to the last column on Windows without it adding a
11. # newline automatically, so reduce the width by one:
12. WIDTH -= 1
13.
14. print('Sine Message, by Al Sweigart al@inventwithpython.com')
15. print('(Press Ctrl-C to quit.)')
16. print()
17. print('What message do you want to display? (Max', WIDTH // 2, 'chars.)')
18. while True:
19.     message = input('> ')
20.     if 1 <= len(message) <= (WIDTH // 2):
21.         break
22.     print('Message must be 1 to', WIDTH // 2, 'characters long.')
23.
24.
25. step = 0.0 # The "step" determines how far into the sine wave we are.
26. # Sine goes from -1.0 to 1.0, so we need to change it by a multiplier:
27. multiplier = (WIDTH - len(message)) / 2
28. try:
29.     while True: # Main program loop.
30.         sinOfStep = math.sin(step)
31.         padding = ' ' * int((sinOfStep + 1) * multiplier)
32.         print(padding + message)
33.         time.sleep(0.1)
34.         step += 0.25 # (!) Try changing this to 0.1 or 0.5.
35. except KeyboardInterrupt:
36.     sys.exit() # When Ctrl-C is pressed, end the program.
```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `math.sin(step)` on line 30 to `math.cos(step)`?
2. What happens if you change `math.sin(step)` on line 30 to `math.sin(0)`?

#68

SLIDING TILE PUZZLE

This classic puzzle relies on a 4×4 board with 15 numbered tiles and one free space. The objective is to slide the tiles until the numbers are in the correct order, going left to right and top to bottom. Tiles can only slide; you're not allowed to directly pick them up and rearrange them. Some versions of this puzzle toy feature scrambled images that form a complete picture once solved.

More information about sliding tile puzzles can be found at https://en.wikipedia.org/wiki/Sliding_puzzle.

The Program in Action

When you run *slidingtilepuzzle.py*, the output will look like this:

Sliding Tile Puzzle, by Al Sweigart al@inventwithpython.com

Use the WASD keys to move the tiles
back into their original order:

```
 1 2 3 4
 5 6 7 8
 9 10 11 12
13 14 15
```

Press Enter to begin...

```
+-----+-----+-----+-----+
| 5 | 10 |  | 11 |
| 6 | 3 | 7 | 2 |
| 14 | 1 | 15 | 8 |
| 9 | 13 | 4 | 12 |
+-----+-----+-----+-----+
```

Enter WASD (or QUIT): (A) (W) (D)
> w

```
+-----+-----+-----+-----+
| 5 | 10 | 7 | 11 |
| 6 | 3 |  | 2 |
| 14 | 1 | 15 | 8 |
| 9 | 13 | 4 | 12 |
+-----+-----+-----+-----+
```

(W)
Enter WASD (or QUIT): (A) (S) (D)
--snip--

How It Works

The data structure that represents the sliding tile game board is a list of lists. The inner lists each represent one column of the 4×4 board and contain strings for the numbered tiles (or the BLANK string to represent the blank space). The `getNewBoard()` function returns this list of lists with all tiles in their starting positions and the blank space in the lower-right corner.

Python can swap the values in two variables with a statement like `a, b = b, a`. The program uses this technique on lines 101 to 108 to swap the blank space and a neighboring tile and simulate sliding a numbered tile into the blank space. The `getNewPuzzle()` function generates new puzzles by performing 200 of these swaps randomly.

```

137. if __name__ == '__main__':
138.     main()

```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Create a more difficult 5×5 variant of the sliding tile puzzle.

- Create a “solve automatically” mode, which saves the current arrangement of the tiles and then attempts up to 40 random moves and stops if they have solved the puzzle. Otherwise, the puzzle loads the saved state and attempts another 40 random moves.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `getNewPuzzle()` on line 22 to `getNewPuzzle(1)`?
2. What happens if you change `getNewPuzzle()` on line 22 to `getNewPuzzle(0)`?
3. What happens if you delete or comment out `sys.exit()` on line 31?

#69

SNAIL RACE

You won't be able to handle the fast-paced excitement of these racing . . . snails. But what they lack in speed they make up for in ASCII-art cuteness. Each snail (represented by an @ character for the shell and v for the two eyestalks) moves slowly but surely toward the finish line. Up to eight snails, each with a custom name, can race each other, leaving a slime trail in their wake. This program is good for beginners.

The Program in Action

When you run *snailrace.py*, the output will look like this:

Snail Race, by Al Sweigart al@inventwithpython.com

```
@v <-- snail

How many snails will race? Max: 8
> 3
Enter snail #1's name:
> Alice
Enter snail #2's name:
> Bob
Enter snail #3's name:
> Carol
START                               FINISH
|                                   |
      Alice
.....@v
      Bob
.....@v
      Carol
.....@v
--snip--
```

How It Works

This program makes use of two data structures, stored in two variables: `snailNames` is a list of strings of each snail's name, and `snailProgress` is a dictionary whose keys are the snails' names and whose values are integers representing how many spaces the snails have moved. Lines 79 to 82 read the data in these two variables to draw the snails at appropriate places on the screen.

```

49.     print(snailName[:MAX_NAME_LENGTH])
50.     print('@v')
51.     snailProgress[snailName] = 0
52.
53. time.sleep(1.5) # The pause right before the race starts.
54.
55. while True: # Main program loop.
56.     # Pick random snails to move forward:
57.     for i in range(random.randint(1, numSnailsRacing // 2)):
58.         randomSnailName = random.choice(snailNames)
59.         snailProgress[randomSnailName] += 1
60.
61.     # Check if a snail has reached the finish line:
62.     if snailProgress[randomSnailName] == FINISH_LINE:
63.         print(randomSnailName, 'has won!')
64.         sys.exit()
65.
66.     # (!) EXPERIMENT: Add a cheat here that increases a snail's progress
67.     # if it has your name.
68.
69.     time.sleep(0.5) # (!) EXPERIMENT: Try changing this value.
70.
71.     # (!) EXPERIMENT: What happens if you comment this line out?
72.     print('\n' * 40)
73.

```

```

74.     # Display the start and finish lines:
75.     print('START' + (' ' * (FINISH_LINE - len('START'))) + 'FINISH')
76.     print('|' + (' ' * (FINISH_LINE - 1) + '|'))
77.
78.     # Display the snails (with name tags):
79.     for snailName in snailNames:
80.         spaces = snailProgress[snailName]
81.         print((' ' * spaces) + snailName[:MAX_NAME_LENGTH])
82.         print(('. ' * snailProgress[snailName]) + '@v')

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Add a “speed boost” that launches the snail four spaces ahead instead of one.
- Add a “sleep mode” that snails can randomly enter during the race. This mode causes them to stop for a few turns and zzz to appear next to them.
- Add support for ties, in case snails reach the finish line at the same time.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `snailName[:MAX_NAME_LENGTH]` on line 81 to `snailNames[0]`?
2. What happens if you change `print('@v')` on line 50 to `print('v@')`?

#70

SOROBAN JAPANESE ABACUS

An abacus, also called a counting frame, is a calculating tool used in many cultures long before electronic calculators were invented.

Figure 70-1 shows the Japanese form of the abacus, called a soroban. Each wire represents a place in a positional numeral system, and the beads on the wire represent the digit at that place. For example, a soroban with two beads moved over on the rightmost wire and three beads moved over on the second-to-rightmost wire would represent the number 32. This program simulates a soroban. (The irony of using a computer to simulate a pre-computer computing tool is not lost on me.)

Figure 70-1: A soroban

Each column in the soroban represents a different digit. The rightmost column is the ones place, the column to its left is the tens place, the column to the left of that is the hundreds place, and so on. The Q, W, E, R, T, Y, U, I, O, and P keys along the top of your keyboard can increase the digit at their respective positions, while the A, S, D, F, G, H, J, K, L, and ; keys will decrease them. The beads on the virtual soroban will slide to reflect the current number. You can also enter numbers directly.

The four beads below the horizontal divider are “earth” beads, and lifting them up against the divider counts as 1 for that digit. The bead above the horizontal divider is a “heaven” bead, and pulling it down against the divider counts as 5 for that digit, so pulling down one heaven bead and pulling up three earth beads in the tens column represents the number 80. More information about abacuses and how to use them can be found at <https://en.wikipedia.org/wiki/Abacus>.

The Program in Action

When you run `soroban.py`, the output will look like this:

```

How It Works

The `displayAbacus()` function accepts a number argument used to figure out where it should render beads on the abacus. The soroban always has exactly 80 possible locations for either '0' beads or '|' rod segments, as marked by the curly braces ({} in the multiline string on lines 127 to 139. Another 10 curly braces represent the digits of the number argument.

We need to create a list of strings to fill in these curly braces, going from left to right, top to bottom. The code in `displayAbacus()` will populate a `hasBead` list with a `True` value to display a '0' bead and a `False` value to display a '|'. The first 10 values in this list are for the top “heaven” row. We’ll put a bead in this row if the column’s digit is 0, 1, 2, 3, or 4, since the heaven bead won’t be in that row unless the digit for that column is 0 to 4. We add Boolean values to `hasBead` for the remaining rows.

Lines 118 to 123 use `hasBead` to create an `abacusChar` list that contains the actual '0' and '|' strings. When combined with `numberList` on line 126, the program forms a `chars` list that populates the curly braces ({} for the multiline-string ASCII art of the soroban.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `abacusNumber = 0` on line 15 to `abacusNumber = 9999`?
2. What happens if you change `abacusChar.append('0')` on line 121 to `abacusChar.append('@')`?

#71

SOUND MIMIC

Similar to the Simon electronic toy, this memorization game uses the third-party `playsound` module to play four different sounds, which correspond to the A, S, D, and F keys on the keyboard. As you successfully repeat the pattern the game gives you, the patterns get longer and longer. How many sounds can you hold in your short-term memory?

If you look at the code, you'll see that the `playsound.playsound()` function is passed the filename of the sound to play. You can download the sound files from these URLs:

<https://inventwithpython.com/soundA.wav>

<https://inventwithpython.com/soundS.wav>

<https://inventwithpython.com/soundD.wav>

<https://inventwithpython.com/soundF.wav>

Place these files in the same folder as *soundmimic.py* before running the program. More information about the *playsound* module can be found at <https://pypi.org/project/playsound/>. Users on macOS must also install the *pyobjc* module from <https://pypi.org/project/pyobjc/> for *playsound* to work.

The Program in Action

When you run *soundmimic.py*, the output will look like this:

```
Sound Mimic, by Al Sweigart al@inventwithpython.com
Try to memorize a pattern of A S D F letters (each with its own sound)
as it gets longer and longer.
Press Enter to begin...
<screen clears>
Pattern: S
<screen clears>
Enter the pattern:
> s
Correct!
<screen clears>
Pattern: S F
<screen clears>
Enter the pattern:
> sf
Correct!
<screen clears>
Pattern: S F F
<screen clears>
Enter the pattern:
> sff
Correct!
<screen clears>
Pattern: S F F D
--snip--
```

How It Works

This program imports the *playsound* module, which can play sound files. The module has one function, *playsound()*, to which you can pass the filename of a *.wav* or *.mp3* file to play. On each round of the game, the program appends a randomly chosen letter (either A, S, D, or F) to the pattern list and plays the sounds in this list. As the pattern list grows longer, so does the pattern of sound files the player must memorize.

61.
62.     if response != pattern:

```

```
63.         print('You scored', len(pattern) - 1, 'points.')
64.         print('Thanks for playing!')
65.         break
66.
67.     time.sleep(1)
```

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you delete or comment out `print('\n' * 60)` on line 47?
2. What happens if you change `response != pattern` on line 62 to `False`?

#72

SPONGECASE

You've probably seen the "Mocking SpongeBob" meme: a picture of SpongeBob SquarePants, with a caption whose text alternates between upper- and lowercase letters to indicate sarcasm, like this: uSiNg SpOnGeBoB MeMeS dOeS NoT mAkE YoU wItTy. For some randomness, the text sometimes doesn't alternate capitalization.

This short program uses the `upper()` and `lower()` string methods to convert your message into "spongecase." The program is also set up so that other programs can import it as a module with `import spongecase` and then call the `spongecase.englishToSpongecase()` function.

tHe PrOgRaM iN ActiOn

When you run `spongecase.py`, the output will look like this:

```
sPoNgEcAsE, bY aL sWeIGaRt Al@iNvEnTwItHpYtHoN.cOm
```

```
eNtEr YoUr MeSsAgE:
```

```
> Using SpongeBob memes does not make you witty.
```

```
uSiNg SpOnGeBoB MeMeS d0eS NoT mAkE YoU wItTy.
```

```
(cOpIed SpOnGeTexT to ClIpb0aRd.)
```

hOw It WoRkS

The code in this program uses a for loop on line 35 to iterate over every character in the message string. The `useUpper` variable contains a Boolean variable to indicate if the character should be made uppercase (if `True`) or lowercase (if `False`). Lines 46 and 47 *toggle* the Boolean value in `useUpper` (that is, set it to its opposite value) in 90 percent of the iterations. This means that the casing almost always switches between upper- and lowercase.

1. What happens if you change `random.randint(1, 100)` on line 46 to `random.randint(80, 100)`?
2. What happens if you delete or comment out `useUpper = not useUpper` on line 47?

#73

SUDOKU PUZZLE

Sudoku is a popular puzzle game in newspapers and mobile apps. The Sudoku board is a 9×9 grid in which the player must place the digits 1 to 9 once, and only once, in each row, column, and 3×3 subgrid. The game begins with a few spaces already filled in with digits, called *givens*. A well-formed Sudoku puzzle will have only one possible valid solution.

The Program in Action

When you run *sudoku.py*, the output will look like this:

```
Sudoku Puzzle, by Al Sweigart al@inventwithpython.com
--snip--
  A B C | D E F | G H I
1  . . . | . . . | . . .
2  . 7 9 | . 5 . | 1 8 .
3  8 . . | . . . | . . 7
   -----+-----+-----
4  . . 7 | 3 . 6 | 8 . .
5  4 5 . | 7 . 8 | . 9 6
6  . . 3 | 5 . 2 | 7 . .
   -----+-----+-----
7  7 . . | . . . | . . 5
8  . 1 6 | . 3 . | 4 2 .
9  . . . | . . . | . . .

Enter a move, or RESET, NEW, UNDO, ORIGINAL, or QUIT:
(For example, a move looks like "B4 9".)
--snip--
```

How It Works

Objects of the `SudokuGrid` class are the data structures that represent the Sudoku grid. You can call their methods to make modifications to, or retrieve information about, the grid. For example, the `makeMove()` method places a number on the grid, the `resetGrid()` method restores the grid to its original state, and `isSolved()` returns `True` if all the solution's numbers have been placed on the grid.

The main part of the program, starting on line 141, uses a `SudokuGrid` object and its methods for this game, but you could also copy and paste this class into other Sudoku programs you create to reuse its functionality.

```

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What error happens if you delete or rename the *sudokupuzzles.txt* file and run the program?
2. What happens if you change `str(y + 1)` on line 91 to `str(y)`?
3. What happens if you change `if y == 2` or `y == 5`: on line 99 to `if y == 1` or `y == 6`:?

#74

TEXT-TO-SPEECH TALKER

This program demonstrates the use of the `pyttsx3` third-party module. Any message you enter will be spoken out loud by your operating system's text-to-speech capabilities. Although computer-generated speech is an incredibly complex branch of computer science, the `pyttsx3` module provides an easy interface for it, making this small program suitable for beginners. Once you've learned how to use the module, you can add generated speech to your own programs.

More information about the `pyttsx3` module can be found at <https://pypi.org/project/pyttsx3/>.

The Program in Action

When you run `texttospechtalker.py`, the output will look like this:

```
Text To Speech Talker, by Al Sweigart al@inventwithpython.com
Text-to-speech using the pyttsx3 module, which in turn uses
the NSSpeechSynthesizer (on macOS), SAPI5 (on Windows), or
eSpeak (on Linux) speech engines.
```

```
Enter the text to speak, or QUIT to quit.
```

```
> Hello. My name is Guido van Robot.
```

```
<computer speaks text out loud>
```

```
> quit
```

```
Thanks for playing!
```

How It Works

This program is short because the `pyttsx3` module handles all of the text-to-speech code. To use this module, install it by following the instructions in this book's introduction. Once you've done so, your Python script can import it with `import pyttsx3` and call the `pyttsx3.init()` function. This returns an `Engine` object that represents the text-to-speech engine. This object has a `say()` method to which you can pass a string of text for the computer to speak when you run the `runAndWait()` method.

```

Exploring the Program

This is a base program, so there aren't many options to customize it. Instead, consider what other programs of yours would benefit from text-to-speech.

#75

THREE-CARD MONTE

Three-card monte is a common scam played on gullible tourists and other easy marks. Three playing cards, one of which is the “red lady” Queen of Hearts, are put face-down on a cardboard box. The dealer quickly rearranges the cards and then asks the mark to pick the Queen of Hearts. But the dealer can use all sorts of tricks to hide the card or otherwise cheat, guaranteeing that the victim never wins. It’s also common for the dealer to have skills in the crowd who secretly work with the dealer but pretend to win the game (to make the victim think they too could win) or purposefully lose badly (to make the victim think they could do much better).

This program shows the three cards and then quickly describes a series of swaps. At the end, it clears the screen, and the player must pick a card.

Can you keep up with the “red lady”? For the authentic three-card monte experience, you can enable the cheat feature, which causes the player to always lose, even if they select the correct card.

The Program in Action

When you run *threecardmonte.py*, the output will look like this:

Three-Card Monte, by Al Sweigart al@inventwithpython.com

Find the red lady (the Queen of Hearts)! Keep an eye on how the cards move.

Here are the cards:

```
|J | |Q | |8 |
|♦ | |♥ | |♣ |
|_J| |_Q| |_8|
```

Press Enter when you are ready to begin...

swapping left and middle...

swapping right and middle...

swapping middle and left...

swapping right and left...

swapping left and middle...

--snip--

<screen clears>

Which card has the Queen of Hearts? (LEFT MIDDLE RIGHT)

> middle

```
|Q | |8 | |J |
|♥ | |♣ | |♦ |
|_Q| |_8| |_J|
```

You lost!

Thanks for playing, sucker!

How It Works

In this program, we use a (*rank, suit*) tuple to represent a playing card.

The rank is a string representing the card number, such as '2', '10', 'Q', or 'K', and the suit is a string of either a heart, club, spade, or diamond emoji.

Since you cannot enter the emoji character using your keyboard, we'll use the `chr()` function calls on lines 16 to 19 to produce them. The tuple ('9', '♦') represents the nine of diamonds.

Instead of printing these tuples directly, the `displayCards()` function on lines 28 to 43 interprets them and displays ASCII-art representations on the screen, like in Project 4, “Blackjack.” The `cards` argument for this function is a list of the playing card tuples, allowing multiple cards to be displayed in a row.

127.     print('Thanks for playing!')
128. else:
129.     print('You lost!')
130.     print('Thanks for playing, sucker!')

```

After entering the source code and running it a few times, try making experimental changes to it. The comments marked with (!) have suggestions for small changes you can make. On your own, you can also try to figure out how to do the following:

- Use the backspace-printing technique from Project 57, “Progress Bar,” to display each swap message briefly and then print `\b` characters to erase it before printing the next one.
- Create a four-card monte game for added difficulty.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `[('Q', HEARTS), getRandomCard(), getRandomCard()]` on line 64 to `[('Q', HEARTS), ('Q', HEARTS), ('Q', HEARTS)]`?
2. What happens if you change `list('23456789JQKA')` on line 49 to `list('ABCDEFGHIIJK')`?
3. What happens if you delete or comment out `time.sleep(DELAY)` on line 93?

#76

TIC-TAC-TOE

Tic-tac-toe is a classic pencil-and-paper game played on a 3×3 grid. Players take turns placing their X or O marks, trying to get three in a row. Most games of tic-tac-toe end in a tie, but it is possible to outsmart your opponent if they're not careful.

The Program in Action

When you run *tictactoe.py*, the output will look like this:

```
Welcome to Tic-Tac-Toe!

  | | 1 2 3
--+--
  | | 4 5 6
--+--
  | | 7 8 9
What is X's move? (1-9)
> 1

X| | 1 2 3
--+--
  | | 4 5 6
--+--
  | | 7 8 9
What is O's move? (1-9)
--snip--
X|O|X 1 2 3
--+--
X|O|O 4 5 6
--+--
O|X|X 7 8 9
The game is a tie!
Thanks for playing!
```

How It Works

To represent tic-tac-toe boards in this program, we use a dictionary with keys '1' through '9' for the spaces on the board. The numbered spaces are arranged in the same way as a phone's keypad. The values in this dictionary are the string 'X' or 'O' for a player's mark and ' ' for an empty space.

```

#77

TOWER OF HANOI

The Tower of Hanoi is a stack-moving puzzle game that features three poles on which you can stack various-sized disks. The object of the game is to move one tower of disks to another pole. However, only one disk can be moved at a time, and larger disks cannot be placed on top of smaller ones. Figuring out a certain pattern will help you solve this puzzle. Can you discover it? (Hint: Try setting the `TOTAL_DISKS` variable to 3 or 4 to solve an easier version first.)

The Program in Action

When you run *towerofhanoi.py*, the output will look like this:

The Tower of Hanoi, by Al Sweigart al@inventwithpython.com

Move the tower of disks, one disk at a time, to another tower. Larger disks cannot rest on top of a smaller disk.

More info at https://en.wikipedia.org/wiki/Tower_of_Hanoi

```
  ||      ||      ||
  @_1@    ||      ||
  @@_2@@  ||      ||

  @@@@@_5@@@@ @_1@  ||
           A      B      C
```

Enter the letters of "from" and "to" towers, or QUIT.
(e.g. AB to moves a disk from tower A to tower B.)

--snip--

How It Works

The data structure that represents a tower is a list of integers. Each integer is the size of the disk. The first integer in the list represents the bottom disk, and the last integer represents the top disk. For example, [5, 4, 2] would represent the following tower:

```
  ||
  ||
  @@_2@@
  @@@@_4@@@@
  @@@@@_5@@@@
```

Python's `append()` and `pop()` list methods can add and remove values from the end of the list, respectively. Just as `someList[0]` and `someList[1]` allow us to access the first and second values in a list, Python lets us use negative indexes to access values from the end of the list using expressions

like `somelist[-1]` and `somelist[-2]`, which access the last and second-to-last values in a list, respectively. This is useful for finding the disk currently at the top of the tower.

```

```

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you delete or comment out lines 73, 74, and 75?
2. What happens if you change `emptySpace = ' ' * (TOTAL_DISKS - width)` on line 100 to `emptySpace = ' '?`
3. What happens if you change `width == 0` on line 102 to `width != 0`?

#78

TRICK QUESTIONS

What does a yellow stone thrown into a blue pond become? Do they have a 4th of July in England? How can a doctor go 30 days without sleep? Whatever you think the answers to these trick questions are, you're probably wrong. The 54 questions in this program have been specifically crafted so that their answers are simple, obvious, and misleading. Finding the true answer will require some cleverness.

Copying the code from this book will spoil the fun, since you'll see the answers, so you might want to download and play this game from <https://inventwithpython.com/trickquestions.py> before looking at the source code.

The Program in Action

When you run *trickquestions.py*, the output will look like this:

Trick Questions, by Al Sweigart al@inventwithpython.com

Can you figure out the answers to these trick questions?

QUESTION: If there are ten apples and you take away two, how many do you have?

ANSWER: **Eight**

Incorrect! The answer is: Two.

Press Enter for the next question...

--snip--

How It Works

The `QUESTIONS` variable holds a list of dictionaries. Each dictionary represents a single trick question and has the keys 'question', 'answer', and 'accept'. The values for 'question' and 'answer' are strings the program displays when it poses the question to the player and reveals the answer, respectively. The value for the 'accept' key is a list of strings. If the player enters a response that contains any of these strings, it's accepted as correct. This allows the player to enter free-form text as their reply. The program is reasonably accurate in detecting when they've provided the correct answer.

Exploring the Program

This is a base program, so there aren't many options to customize it. Instead, consider other uses for a question-and-answer program format.

#79

TWENTY FORTY-EIGHT

Gabriele Cirulli, a web developer, invented the game 2048 in one weekend. It was inspired by Veewo Studios' 1024 game, which in turn was inspired by Threes!, a game by the development team Sirvo. In 2048, you must merge numbers on a 4×4 board to clear them from the screen. Two 2s merge into a 4, two 4s merge into an 8, and so on. The game adds a new 2 to the board on each merging. The objective is to reach 2048 before the entire board fills up.

The Program in Action

When you run *twentyfortyeight.py*, the output will look like this:

```
Twenty Forty-Eight, by Al Sweigart al@inventwithpython.com
--snip--
+-----+

How It Works

This program implements its sliding behavior using “column” data structures, represented by lists of four strings: BLANK (a single-space string), '2', '4', '8', and so on. The first value in this list represents the bottom of the column, while the last represents the top. Numbers that combine in a column always slide downward, whether the player slides the tiles up, down, left, or right. Think of it as gravity pulling the tiles in these directions. For example, Figure 79-1 shows a board with tiles sliding to the right. We'll create four lists to represent the columns:

- ['2', '4', '8', ' ']
- [' ', ' ', ' ', '4']
- [' ', ' ', ' ', '2']
- [' ', ' ', ' ', ' ']

The `combineTilesInColumn()` function accepts one column list and returns another, with the matching numbers combined and shifted toward the bottom. The code that calls `combineTilesInColumn()` handles creating the column lists in the appropriate direction and updating the game board with the returned list.

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `return score` on line 118 to `return 9999`?
2. What happens if you change `board[randomSpace] = 2` on line 229 to `board[randomSpace] = 256`?

#80

VIGENÈRE CIPHER

The Vigenère cipher, misattributed to 19th-century cryptographer Blaise de Vigenère (others had independently invented it earlier), was impossible to crack for hundreds of years. It is essentially the Caesar cipher, except it makes use of a multipart key. The so-called *Vigenère key* is a word, or even a random series of letters. Each letter represents a number by which to shift the letter in the message: *A* represents shifting a letter in the message by 0, *B* represents 1, *C* represents 2, and so on.

For example, if a Vigenère key is the word “CAT,” the *C* represents a shift of 2, the *A* represents 0, and the *T* represents 19. The first letter of the message gets shifted by 2, the second letter by 0, and the third letter by 19. For the fourth letter, we repeat the key of 2.

This use of multiple Caesar cipher keys is what gives the Vigenère cipher its strength. The possible number of combinations is too big to brute force.

At the same time, the Vigenère cipher doesn't suffer from the frequency analysis weakness that can crack the simple substitution cipher. For centuries, the Vigenère cipher represented the state of the art in cryptography.

You'll notice many similarities between the code for the Vigenère and Caesar cipher programs. More info about the Vigenère cipher can be found at https://en.wikipedia.org/wiki/Vigen%C3%A8re_cipher. If you'd like to learn more about ciphers and code breaking, you can read my book *Cracking Codes with Python* (No Starch Press, 2018; <https://nostarch.com/crackingcodes/>).

The Program in Action

When you run `vigener.py`, the output will look like this:

```
Vigenère Cipher, by Al Sweigart al@inventwithpython.com
The Vigenère cipher is a polyalphabetic substitution cipher that was
powerful enough to remain unbroken for centuries.
Do you want to (e)ncrypt or (d)ecrypt?
> e
Please specify the key to use.
It can be a word or any combination of letters:
> PIZZA
Enter the message to encrypt.
> Meet me by the rose bushes tonight.
Encrypted message:
Bmds mt jx sht znre qcrgeh bnmivps.
Full encrypted text copied to clipboard.
```

How It Works

Because the encryption and decryption processes are fairly similar, the `translateMessage()` function handles both of them. The `encryptMessage()` and `decryptMessage()` functions are merely *wrapper functions* for `translateMessage()`. In other words, they are functions that adjust their arguments, forward these to another function, and then return that function's return value. This program uses these wrapper functions so that they can be called in a manner similar to `encryptMessage()` and `decryptMessage()` in Project 66, "Simple Substitution Cipher." You can import these projects as modules in other programs to make use of their encryption code without having to copy and paste the code directly into your new program.

```

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens when you encrypt with the key 'A'?
2. What error do you cause when you delete or comment out `myKey = response` on line 40?

#81

WATER BUCKET PUZZLE

In this solitaire puzzle game, you must use three buckets (three-liter, five-liter, and eight-liter buckets) to collect exactly four liters of water in one of the buckets. Buckets can only be emptied, completely filled, or poured into another bucket. For example, you can fill the five-liter bucket and then pour its contents into the three-liter bucket, leaving you with a full three-liter bucket and two liters of water in the five-liter bucket.

With some effort, you should be able to solve the puzzle. But can you figure out how to solve it with the minimal number of moves?

The Program in Action

When you run `waterbucket.py`, the output will look like this:

Water Bucket Puzzle, by Al Sweigart al@inventwithpython.com

Try to get 4L of water into one of these buckets:

```
8|      |
7|      |
6|      |
5|      | 5|      |
4|      | 4|      |
3|      | 3|      | 3|      |
2|      | 2|      | 2|      |
1|      | 1|      | 1|      |
+-----+ +-----+ +-----+
      8L      5L      3L
```

You can:

- (F)ill the bucket
- (E)mpty the bucket
- (P)our one bucket into another
- (Q)uit

```
> f
Select a bucket 8, 5, 3, or QUIT:
> 5
```

Try to get 4L of water into one of these buckets:

```
8|      |
7|      |
6|      |
5|      | 5| WWWWWW|
4|      | 4| WWWWWW|
3|      | 3| WWWWWW| 3|      |
2|      | 2| WWWWWW| 2|      |
1|      | 1| WWWWWW| 1|      |
+-----+ +-----+ +-----+
      8L      5L      3L
--snip--
```

How It Works

The `waterInBucket` variable stores a dictionary that represents the state of the water buckets. The keys to this dictionary are the strings `'8'`, `'5'`, and `'3'` (representing the buckets), and their values are integers (representing the liters of water in that bucket).

Lines 48 to 59 use this dictionary to render the buckets and water on the screen. The `waterDisplay` list contains either `'WWWWW'` (representing water) or `' '` (representing air) and is passed to the `format()` string

method. The first eight strings in the `waterDisplay` list fill the eight-liter bucket, the next five strings the five-liter bucket, and the final three strings the three-liter bucket.

127.
128.     elif move == 'C':
129.         pass # If the player selected Cancel, do nothing.

```

After entering the source code and running it a few times, try making experimental changes to it. On your own, you can also try to figure out how to do the following:

- Add variety by making the game configurable so you can specify any sizes for the three buckets and any amount for the goal quantity.
- Add a “hint” that examines the amount of water in each bucket and provides the next step to take. If the program can’t figure out which action to take next, it can simply display “I don’t know what you should do next. Maybe start over?”

Exploring the Program

Try to find the answers to the following questions. Experiment with some modifications to the code and rerun the program to see what effect the changes have.

1. What happens if you change `waterInBucket[srcBucket] = 0` on line 104 to `waterInBucket[srcBucket] = 1`?
2. What happens if you change `{'8': 0, '5': 0, '3': 0}` on line 16 to `{'8': 0, '5': 4, '3': 0}`?
3. What happens if you change `{'8': 0, '5': 0, '3': 0}` on line 16 to `{'8': 9, '5': 0, '3': 0}`?

A

TAG INDEX

The projects in this book are marked with a set of tags that describe the type of program they are. The first tag indicates their size: tiny (1 to 63 lines), short (64 to 127 lines), large (128 to 255 lines), and extra-large (256 lines or more). The size tags are as follows:

tiny: #3 Bitmap Message, #7 Caesar Hacker, #12 Collatz Sequence, #14 Countdown, #15 Deep Cave, #16 Diamonds, #19 Digital Clock, #20 Digital Stream, #24 Factor Finder, #25 Fast Draw, #31 Guess the Number, #32 Gullible, #35 Hex Grid, #40 Leetspeak, #42 Magic Fortune Ball, #46 Million Dice Roll Statistics Simulator, #49 Multiplication Table, #50 Ninety-Nine Bottles, #52 Numeral Systems Counter, #56 Prime Numbers, #57 Progress Bar, #58 Rainbow, #60 Rock Paper Scissors (Always-Win Version), #61 ROT13 Cipher, #65 Shining Carpet, #67 Sine Message, #72 sPoNgEcAsE, #74 Text-To-Speech Talker

short: #1 Bagels, #2 Birthday Paradox, #5 Bouncing DVD Logo, #6 Caesar Cipher, #8 Calendar Maker, #10 Cho-Han, #13 Conway's Game of Life, #18 Dice Roller, #21 DNA Visualization, #26 Fibonacci, #29 Forest Fire Sim, #51 niNety nniinE BoOttels, #53 Periodic Table of the Elements, #54 Pig Latin, #55 Powerball Lottery, #59 Rock Paper Scissors, #64 Seven-Segment Display Module, #66 Simple Substitution Cipher, #69 Snail Race, #71 Sound Mimic, #76 Tic-Tac-Toe, #77 Tower of Hanoi, #80 Vigenère Cipher

large: #4 Blackjack, #9 Carrot in a Box, #11 Clickbait Headline Generator, #17 Dice Math, #22 Ducklings, #23 Etching Drawer, #28 Flooder, #30 Four in a Row, #33 Hacking Minigame, #34 Hangman and Guillotine, #36 Hourglass, #37 Hungry Robots, #39 Langton's Ant, #41 Lucky Stars, #43 Mancala, #44 Maze Runner 2D, #47 Mondrian Art Generator, #48 Monty Hall Problem, #62 Rotating Cube, #63 Royal Game of Ur, #68 Sliding Tile Puzzle, #70 Soroban Japanese Abacus, #73 Sudoku Puzzle, #75 Three-Card Monte, #78 Trick Questions, #79 Twenty Forty-Eight, #81 Water Bucket Puzzle

extra-large: #27 Fish Tank, #38 J'accuse!, #45 Maze Runner 3D

The remaining tags indicate the features of the program:

artistic: #3 Bitmap Message, #5 Bouncing DVD Logo, #13 Conway's Game of Life, #14 Countdown, #15 Deep Cave, #16 Diamonds, #17 Dice Math, #19 Digital Clock, #20 Digital Stream, #21 DNA Visualization, #22 Ducklings, #23 Etching Drawer, #27 Fish Tank, #33 Hacking Minigame, #35 Hex Grid, #36 Hourglass, #39 Langton's Ant, #45 Maze Runner 3D, #47 Mondrian Art Generator, #58 Rainbow, #62 Rotating Cube, #65 Shining Carpet, #67 Sine Message, #69 Snail Race, #70 Soroban Japanese Abacus

beginner: #3 Bitmap Message, #6 Caesar Cipher, #7 Caesar Hacker, #9 Carrot in a Box, #10 Cho-Han, #11 Clickbait Headline Generator, #12 Collatz Sequence, #15 Deep Cave, #16 Diamonds, #20 Digital Stream, #24 Factor Finder, #25 Fast Draw, #31 Guess the Number, #32 Gullible, #35 Hex Grid, #40 Leetspeak, #42 Magic Fortune Ball, #46 Million Dice Roll Statistics Simulator, #49 Multiplication Table, #50 Ninety-Nine Bottles, #58 Rainbow, #65 Shining Carpet, #69 Snail Race, #71 Sound Mimic, #72 sPoNgEcAsE, #74 Text-To-Speech Talker

B

CHARACTER MAP

The `print()` function allows you to easily make any character you can type on the keyboard appear on the screen. However, there are many other characters you may like to display: the hearts, diamonds, clubs, and spades card suits; lines; shaded boxes; arrows; music notes; and so on. You can obtain string values of these characters by passing their numeric code, called a Unicode code point, to the `chr()` function. Text is stored on computers as a series of numbers, with each character represented by a different number. This appendix contains a list of such code points.

Using the chr() and ord() Functions

Python's built-in `chr()` function accepts an integer argument and returns a string of the number's character. The `ord()` function does the opposite: it accepts a string argument of a single character and returns the character's number. This number is the code point for the character in the Unicode standard.

For example, enter the following into the interactive shell:

```
>>> chr(65)
'A'
>>> ord('A')
65
>>> chr(66)
'B'
>>> chr(9829)
'♥'
```

Not all numbers are valid code points for printable characters. The terminal windows that show the text output of programs may be limited in which characters they can display. The font the terminal window uses also must support the character your program prints. The terminal window prints a Unicode replacement character, `◆`, for any character it is unable to print.

Windows' terminal window has a far more limited range of characters it can display. This set is known as the Windows Glyph List 4, and it appears in this appendix and on Wikipedia at https://en.wikipedia.org/wiki/Windows_Glyph_List_4.

The code points for characters are often listed with a base-16 hexadecimal number, as opposed to the base-10 decimal numbers we are used to. Instead of the decimal digits 0 to 9, hexadecimal has the digits 0 to 9 and then continues with the letters A to F. Hexadecimal numbers are often written with a `0x` prefix to denote that the number that follows is in hex.

You can convert a decimal integer value to a string of the hexadecimal number with the `hex()` function. You can convert a string of the hexadecimal number to a decimal integer with the `int()` function, passing 16 as the second argument. For example, enter the following into the interactive shell:

```
>>> hex(9)
'0x9'
>>> hex(10)
'0xa'
>>> hex(15)
'0xf'
>>> hex(16)
'0x10'
>>> hex(17)
'0x11'
>>> int('0x11', 16)
17
```

```
>>> int('11', 16)
17
```

When calling the `chr()` function, you must pass a decimal integer as the argument, not a hexadecimal string.

Table of Code Points

The following are all the Unicode code points in the set known as Windows Glyph List 4, which are the characters supported by the Windows terminal program, Command Prompt. Both macOS and Linux can display more characters than are in this list, but to keep your Python programs compatible, I recommend you stick to the characters in this table.

Never before has the world relied so heavily on the Internet to stay connected and informed. That makes the Electronic Frontier Foundation's mission—to ensure that technology supports freedom, justice, and innovation for all people—more urgent than ever.

For over 30 years, EFF has fought for tech users through activism, in the courts, and by developing software to overcome obstacles to your privacy, security, and free expression. This dedication empowers all of us through darkness. With your help we can navigate toward a brighter digital future.

CREATIVE PROJECTS FOR CODING NOVICES

If you've mastered basic Python syntax and you're ready to start writing programs, you'll find *The Big Book of Small Python Projects* both enlightening and fun. This collection of 81 Python projects will have you making digital art, games, animations, counting programs, and more right away. Once you see how the code works, you'll practice re-creating the programs and experiment by adding your own custom touches.

These simple, text-based programs are 256 lines of code or less. And whether it's a vintage screensaver, a snail-racing game, a clickbait headline generator, or animated strands of DNA, each project is designed to be self-contained so you can easily share it online.

You'll create:

- *Hangman*, *Blackjack*, and other games to play against your friends or the computer
- Simulations of a forest fire, a million dice rolls, and a Japanese abacus

- Animations like a virtual fish tank, a rotating cube, and a bouncing DVD logo screensaver
- A first-person 3D maze game
- Encryption programs that use ciphers like ROT13 and Vigenère to conceal text

If you're tired of standard step-by-step tutorials, you'll love the learn-by-doing approach of *The Big Book of Small Python Projects*. It's proof that good things come in small programs!

ABOUT THE AUTHOR

Al Sweigart is a professional software developer who teaches programming to kids and adults. He has written several bestselling programming books for beginners, including *Automate the Boring Stuff with Python*, *Beyond the Basic Stuff with Python*, *Invent Your Own Computer Games with Python*, *Cracking Codes with Python*, and *Coding with Minecraft* (all from No Starch Press).
